## 1 INTRODUCTION

In February 2002, De Beers Canada Mining Inc. (De Beers) submitted an Environmental Assessment (EA) for the Snap Lake Diamond Project to the Mackenzie Valley Environmental Impact Review Board (MVEIRB). The mitigation and monitoring section of the Environmental Health component of the EA (Section 11.3.2.5) included a commitment by De Beers to conduct further soil characterization and analysis to reduce the uncertainty associated with baseline exposure of aluminum by wildlife (De Beers 2002). In addition, baseline data were required to better characterize soil metals and polycyclic aromatic hydrocarbon (PAH) concentrations within 11 km of the Snap Lake Diamond Project. In August 2002, soil sampling was conducted and submitted for chemical analyses. This report describes the results of the soil sampling program and addresses the commitments made by De Beers in the EA.

### 1.1 OBJECTIVES

The objective of the soil sampling program was to answer two questions as follows:

- Question #1: What are the baseline concentrations of metals and PAHs in soil within 11 km of the proposed mine site?
- Question #2: How much aluminum in soil in the Local Study Area (LSA) and Regional Study Area (RSA) is available for uptake into animals?

Baseline data collected during the spring of 2001 did not include sampling locations within 11 km of the Snap Lake Diamond Project. Data from this area are necessary for comparison with the results of future monitoring programs (if necessary). In the EA, it was assumed that regional soil concentrations (i.e., 11 to 30 km from the mine) represent concentrations within the vicinity of the mine (i.e., within 11 km). While this was a sound assumption, it is possible that concentrations of some metals may be different in areas closer to the mine due to variations in geological conditions. Therefore, detailed baseline soil data for the area within the mine footprint and within 11 km of the mine footprint were collected in 2002.

In the EA, measured and predicted soil aluminum concentrations were estimated to have a potential health risk for some wildlife receptors in both the LSA and

RSA for baseline and application cases<sup>1</sup>. However, the risk assessment assumed 100% availability. The calculated risk is likely to have been substantially overestimated because aluminum is naturally abundant in soil. Most naturally occurring aluminum is tightly bound to soil particles and not available for uptake by plants and wildlife. Because baseline data on soil characteristics that affect aluminum availability were not available, a conservative approach (i.e., assuming 100% availability) was used in the assessment. Aluminum availability in soil is dependent on soil pH, organic content, and the presence of cations such as magnesium. The amount of available aluminum present in soils from the Snap Lake area was quantified and used to re-calculate aluminum exposure in this report to provide a more realistic estimate of the risk from aluminum exposure.

## 1.2 STRUCTURE OF THE REPORT

The remainder of the report is structured as follows:

- Section 2, Field Program Methods, provides a description of the field sampling program conducted in August 2002.
- Section 3, Baseline Results, provides a summary of the results of the field program that address Question #1 and compares data obtained during the August 2002 field program with data obtained during the June 2001 field program.
- Section 4, Aluminum Bioavailability, provides a summary of the results of the field program that address Question #2. Results of the re-evaluation of wildlife exposures to aluminum are also presented.
- Section 5, Conclusions, provides a brief summary of the report.

---

<sup>1</sup> The baseline case assessment was based on exposure to chemical emissions from existing sources (i.e., naturally occurring and anthropogenic). The application case assessment was based on exposure to chemical emissions from the combination of baseline sources and the Snap Lake Diamond Project operational phase.

## 2 FIELD PROGRAM METHODS

Prior to the field investigation, sampling locations were randomly selected using a geographical information system (GIS) program that selected four sampling locations within three rings; 0 to 1 km, >1 to 5 km, and >5 to 11 km from the footprint boundary of the Snap Lake Diamond Project. The rings are arbitrary boundaries located at increasing distances from the project footprint to allow a comparison of concentration versus distance. Each of the four random sampling locations (identified as a green dot in Figure 1) within each ring is a plot. For example, there are four plots between the 5-km and 11-km rings. Within each plot, two or three soil samples were collected for metals and one sample was collected for PAH analysis. One quality assurance/quality control (QA/QC) split sample was collected within each ring.

In addition, the following locations were systematically chosen as sampling locations (identified as purple dots in Figure 1) because they may be impacted by dust when the project is in operation:

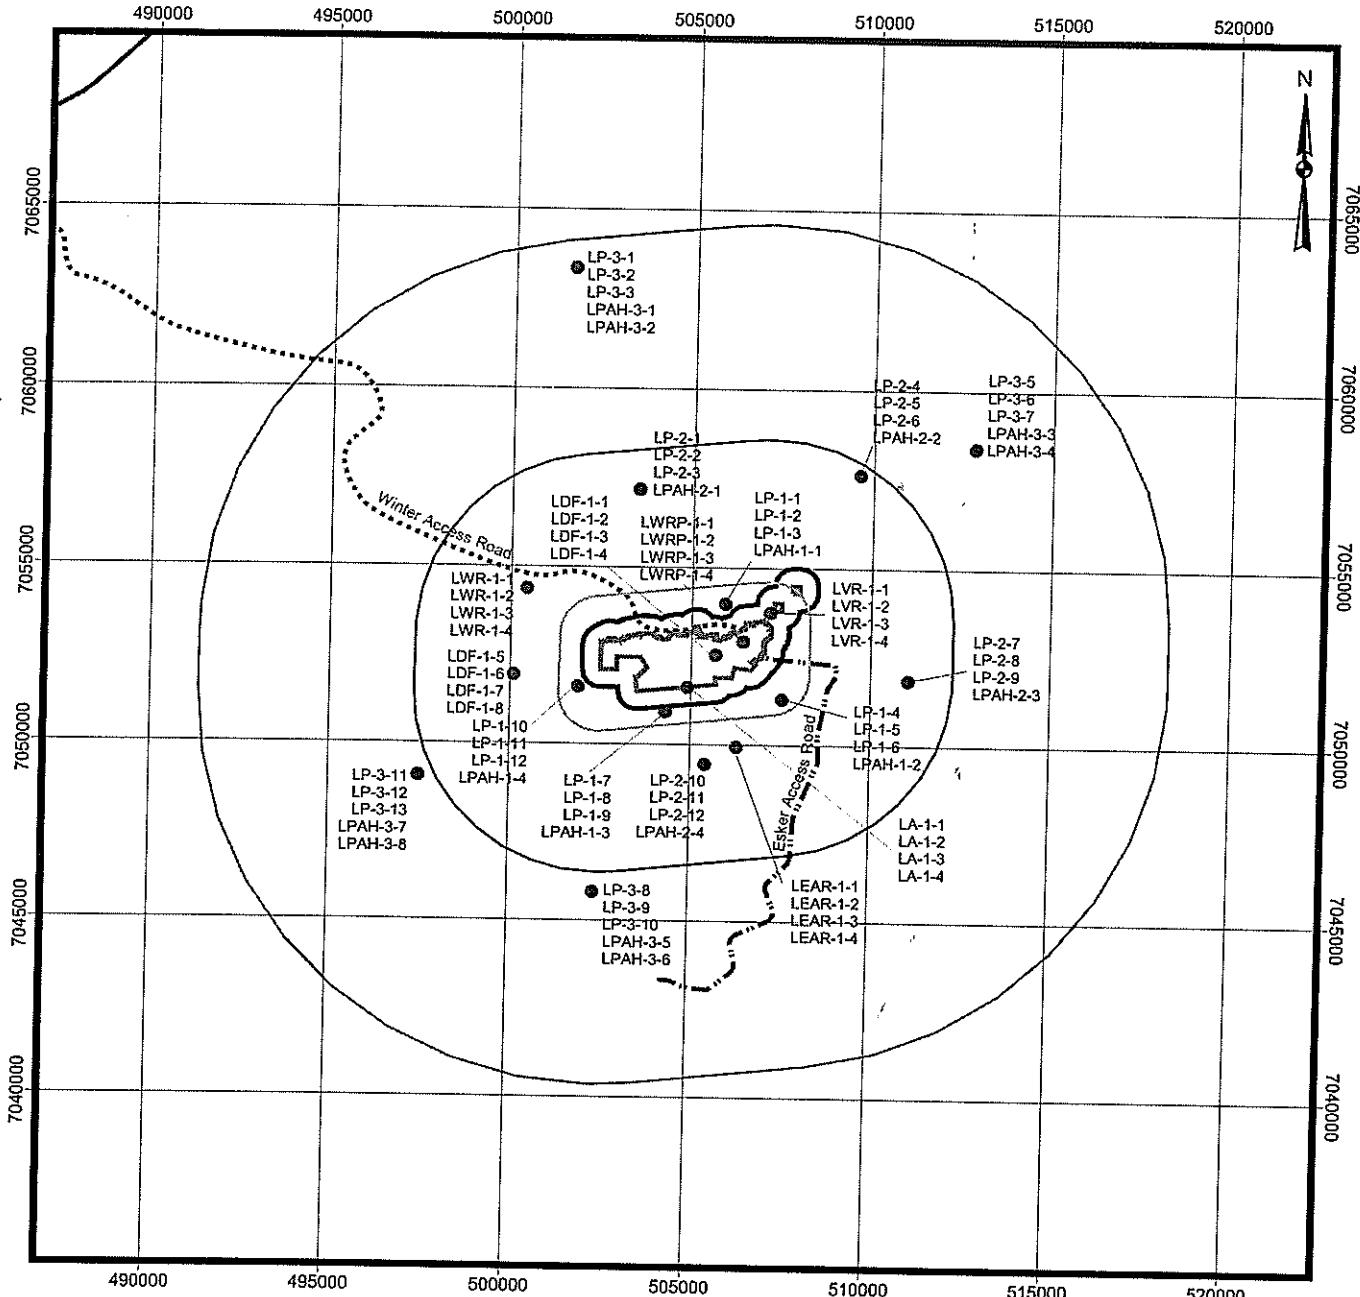

- next to the airstrip;
- near the future north pile (i.e., waste rock storage);
- near the future vent raises on the north shore;
- near the dust fall monitoring locations within the mine footprint and in the reference location;
- near the esker access road; and
- near the winter access road.

One soil sample was collected at each of the systematic sampling locations with the exception of the future north pile where three samples were collected and the future vent raises where two samples were collected. No QA/QC samples were collected in the systematic sampling locations. Soil sampling locations are presented in Figure 1.

The soil sampling program was carried out between August 12 to 14, 2002. Methods used for the soil sampling program were based on Golder Standard Operating Procedures (Golder 1995) and on methods used previously for trace metals analyses (Golder 1998; Golder 2000). Detailed methods are presented in Appendix I. Briefly, a nylon trowel was used to collect all soil samples. The trowel was rinsed in 10% nitric acid and deionized water between each sample. Field staff wore nitrile gloves while collecting samples, and changed gloves between samples. Soil depth and type were recorded for each sample location. All samples were collected from the top 10 cm of the soil horizon. Samples were placed in plastic bags (for metals analysis) or glass jars (for PAH analysis) and stored in a cooler with ice packs until access to a refrigerator was possible. All

---

samples were stored at approximately 4°C until shipment to the laboratory. Samples were submitted to EnviroTest Laboratories (ETL) for analysis of total metals, major ions, PAHs, aluminum in saturated paste, cation exchange capacity, organic and inorganic carbon, and pH. Analytical methods, including QA/QC measures, are presented in Appendix II.

### 3 BASELINE RESULTS

This section provides a summary of the results of the field program that address Question #1: What are the baseline concentrations of metals and polycyclic aromatic hydrocarbons (PAHs) in soil within 11 km of the proposed mine site? It also compares data obtained during the August 2002 field program with data obtained during the June 2001 field program.

Concentrations of all samples collected during the 2002 field program are presented in Tables 1 to 6. Concentrations of metals were similar between the systematic sample locations and the random sample locations. Concentrations of PAHs were less than analytical detection limits for all samples except for naphthalene at the dustfall on-site location, and naphthalene and phenanthrene at the dustfall reference location. Naphthalene and phenanthrene were marginally above the detection limit in these two locations.

There was no apparent relationship between distance from the mine and concentration of metals (Figures I-1 to I-23 in Appendix III). This relationship could not be determined for mercury, selenium and silver since concentrations of these metals were mainly less than the detection limits.

To determine if the baseline data used in the EA were representative of soil concentrations within 11 km of the mine footprint, the 2002 data were compared with data collected in 2001 (i.e., data presented in the Snap Lake Diamond Project EA) using SYSTAT® and Statistix® statistics software packages. Since there was no relationship between distance from the mine and concentration of metals, the statistical tests were conducted only for the chemicals of concern (COCs) identified in the EA (i.e., aluminum, barium, chromium, manganese, strontium, thallium, and naphthalene). The COCs are the substances that are expected to increase in concentration during the operation of the Snap Lake Diamond Project. For a detailed description of the COC screening process, refer to Appendix XI, Section 4.1.2 of the EA (De Beers 2002).

The Lilliefors test for normality and the Bartlett's test for equal variances were used for each year of data. These tests indicated that the data were normally distributed and that the variability was similar for both years. Data from 2001 and 2002 were then compared using a one-way Analysis of Variance (ANOVA) to determine if the data from 2002 were statistically similar to the 2001 data used in the EA. There was no significant difference between the 2001 and 2002 data ( $p>0.05$ ), with the exception of aluminum and chromium. Concentrations of aluminum and chromium were significantly lower in 2002 than 2001 (i.e., concentrations were less within 11-km of the mine footprint).

Pyrene	0.01	<0.01	<0.01	<0.01	<0.01	<0.01	<0.01
Quinoline	0.01	<0.01	<0.01	<0.01	<0.01	<0.01	<0.01

<sup>1</sup> Sample identification in the De Beers' database includes zero placemarks (e.g., SPAH-001-001).<sup>2</sup> Dustfall Reference location was accidentally given the same identification as the dustfall on-site sample. Samples were differentiated by date sampled.

Note: PAH analysis was not done for the Waste Rock Pile location because this area was sampled in 2001 and all PAHs were less than analytical detection limits.

## 4 ALUMINUM BIOAVAILABILITY

This section provides a summary of the results of the field program that address Question #2: How much aluminum in soil in the LSA and RSA is available for uptake into animals? In addition to the standard total metals analysis, all of the soil samples collected were analyzed by saturated paste extraction for aluminum. Soil analysis for total metals requires preparation of the samples with strong acid solutions that essentially strip tightly bound metals from the soil grains. The saturated paste method uses water for the preparation of the sample, which simulates removal of only those metals that are water soluble and in the form that can be readily taken up by animals. Therefore, an adjustment can be made to the exposure calculations used to predict risks in the EA to estimate a more realistic aluminum exposure.

Results of the analysis of aluminum by both the saturated paste extraction and the total analysis are presented in Table 8. Concentrations of soluble aluminum range from 0.48 to 6.95 mg/L (equivalent to mg/kg). These values represent less than 0.06% of the total aluminum present in the soils and are typical of soils with similar pH and organic matter content (Kabata-Pendias 2001). While available aluminum concentrations are usually higher in acid soils, there was no correlation of the saturated paste results with pH (Appendix IV). The lack of correlation with pH indicates that other parameters such as organic matter content and cation exchange capacity are also acting to reduce aluminum availability (Kabata-Pendias 2001). Therefore, available aluminum is only a small proportion of the total aluminum measured in these soils.

Based on the reduced availability and the lower baseline concentration measured during the 2002 field season, risk estimates due to aluminum exposure were recalculated for caribou, grizzly bear, wolverine, Arctic ground squirrel and ptarmigan (i.e., value ecosystem components [VECs] for which risks were predicted in the EA).

The risk estimates were calculated using the same methods described in Appendix XI, Section 3 of the EA (De Beers 2002). Briefly, exposure was calculated for each VEC according to the amount of time they spend in the area, food and soil ingestion rates, and body weight. The exposure was compared with a toxicity benchmark provided from toxicity studies using laboratory animals. The product of the comparison is called an exposure ratio (ER). The ER is calculated using the following equation:

$$\text{ER} = \text{Estimated Exposure} \div \text{Benchmark Dose}$$

ERs less than one indicate that exposures to COCs are unlikely to cause adverse effects to wildlife. An ER greater than one indicates that there is a potential for adverse effects on wildlife.

All assumptions used in the EA were also used for the re-calculation of ERs, except the assumption for aluminum availability, which was adjusted based on the data collected in 2002. Aluminum availability from soil was conservatively assumed to be 1% to account for additional available aluminum that may not have been captured by the saturated paste method. This is a very conservative assumption since the saturated paste method is well-recognized method for estimation of availability (Abboud, pers. comm; Kabata-Pendias 2001). The re-calculation of risk also included 2002 data for vascular plants and lichen, which were collected at the same time as the soil and are presented in Appendix V.

The comparison between the ERs presented in the EA and the ERs calculated based on the 2002 data are presented in Tables 9 and 10.

**Table 9 Comparison Between Estimated Risks for Aluminum Presented in the EA and Re-Calculated Estimated Risks Based on 2002 Data for Wildlife That Inhabit Both the Local Study Area and Regional Study Area**

Valued Ecosystem Component	Baseline		Application	
	2001	2002	2001	2002
Caribou	1.4	0.8	1.4	0.8
Grizzly Bear	1.6	0.1	1.9	0.1
Wolverine	1.2	0.01	1.2	0.01

**Table 10 Comparison Between Estimated Risks for Aluminum Presented in the EA and Re-Calculated Estimated Risks Based on 2002 Data for Wildlife that Live Entirely Within the Local Study Area or Regional Study Area**

Valued Ecosystem Component	Local Study Area				Regional Study Area			
	Baseline		Application		Baseline		Application	
	2001	2002	2001	2002	2001	2002	2001	2002
Arctic ground squirrel	6.3	0.6	7.7	0.6	6.3	0.6	7.7	0.6
Ptarmigan	0.9	0.06	1.0	0.06	0.9	0.06	1.0	0.06

ERs are less than one for all VECs for both baseline and application case exposures to aluminum. These ERs were calculated using more realistic exposure assumptions than used for the EA (i.e., adjustment for availability of aluminum from soil). In addition, Arctic ground squirrel, ptarmigan, and grizzly bear exposures were based on aluminum concentrations in vascular plants rather than lichen (i.e., lichen was assumed in the EA).

These re-calculated ERs supercede those presented in the EA. The VECs for which new ERs were calculated are considered to be representative of all of the VECs evaluated in the EA since their intake of plants and soils is greater than the other VECs.

The new ERs using updated baseline data and more realistic bioavailability assumptions show that wildlife health risks are not expected to occur due to the operation of the Snap Lake Diamond Project.

## 5 CONCLUSIONS

During the August 2002 Environmental Health field program, soil samples were collected and submitted to ETL for chemical analyses. The purpose of the program was to address commitments made by De Beers in the EA and to answer two questions:

- Question #1: What are the baseline concentrations of metals and PAHs in soil within 11 km of the proposed mine site?
- Question #2: How much aluminum in soil in the LSA and RSA is available for uptake into animals?

The baseline concentrations of metals and PAHs in soils in the Local Study Area (LSA) are provided in Tables 1 to 7. There was no significant difference between the 2001 (Regional Study Area) and 2002 (LSA) baseline data. The exceptions were concentrations of aluminum and chromium, which were significantly lower in 2002 than 2001. The 2002 data illustrate the importance of establishing the local (<11 km) baseline concentrations prior to future monitoring programs. The data indicate that different geological conditions within the LSA have produced lower baseline concentrations of aluminum and chromium than in the RSA.

Aluminum availability is less than 1% in soil samples collected in 2002. Based on the reduced availability and lower baseline concentrations measured in 2002, potential risks due to aluminum exposures were re-calculated for caribou, grizzly bear, wolverine, Arctic ground squirrel, and ptarmigan. All ERs are less than one for all VECs for both baseline and application case exposures to aluminum (i.e., exposure is calculated to be less than the toxicity benchmark). Therefore, wildlife health risks are not expected to occur due to the operation of the Snap Lake Diamond Project.

Chromium ERs were not re-calculated since all ERs were less than 1 in the EA. The ERs in the EA were produced using the higher 2001 baseline data. Therefore, any re-calculated ERs would remain less than 1 using 2002 data.

## 6 CLOSURE

We trust the above meets your present requirements. If you have any questions or require additional details, please contact the undersigned.

**APPENDIX I**  
**SOIL SAMPLING METHODS**

**GOLDER ASSOCIATES LTD.  
SPECIFIC WORK INSTRUCTIONS**

**SPECIFIC WORK INSTRUCTIONS****SWI No: 3****Project: DeBeers EIA****Date: August 1, 2002****Author: Cindy Robinson****Project Manager: Dave Caughill****To: Conrad Pilon****cc:** File**File No.:****Subject: Soil Sampling for Chemical Analysis****Job/Task No.: 5700****Scope of Work/Specific Instructions:**

**Objective:** The objective of the soil sampling is to determine metal and PAH concentrations in areas within 11 km of the site.

**Supplies:** Clean ziploc sample bags. Glass sample jars. Disposable nitrile gloves. Plastic (nylon) trowel. Pre-printed labels and extra labels. Dry J-cloths. Cooler.

**Sampling Instructions:**

- 1) Label ziploc bags and glass jars with the sample number (as identified in the attached sample number list), location and date.
- 2) Use nitrile gloves for all contact with soil and change gloves between samples.
- 3) Clean trowel with a J-cloth soaked with 10% nitric acid (5% nitric acid is fine if that is what is available at the mine site) and then with another J-cloth soaked in distilled water. Dry the trowel with a clean J-cloth.
- 4) Using the trowel test for soil depth. Record soil depth. Take the sample from the full soil depth if less than 10 cm deep. If greater than 10 cm, take the sample from the top 10 cm layer. Record the soil characteristics (see attached soil sample identification form). Note GPS location. Take close-up photo of soil sample site. Fill the ziploc bag  $\frac{1}{4}$  to  $\frac{1}{2}$  full with soil (at least 200 g). And fill a labelled jar.
- 5) Squeeze air out of the bag and seal closed. Place inside another ziploc bag, place a more detailed paper label inside the outer bag and seal closed.
- 6) In between samples, clean the trowel with a J-cloth soaked with 10% nitric acid (or 5%) and then with another J-cloth soaked in distilled water. Dry the trowel with a clean J-cloth.
- 7) If possible, bring a cooler and ice packs with you in the field to store the samples in during the day. Soil samples must be packed in a cooler with ice packs for transport to the lab. If there is no space for a cooler, place samples in a clean garbage bag and keep as cool as possible.

8) At one sample site, collect a QA/QC split sample. Specify which sample is split in field notes. Mix the sample by stirring and shaking in the bag. Split and label the two bags and two jars using the same sample number scheme as for regular samples.

Precautions: Make sure soil is always handled by gloved hands and never by anything made of metal (unless thoroughly acid washed). Change gloves between samples.

**Sampling Locations:**

- 1) Collect 2 soil samples from each of the lichen sampling locations (i.e., each plot) unless there is no soil available (i.e., boulder/bedrock areas). At one plot collect 3 soil samples.
- 2) You may have to collect soil from more than one area if the only soil occurs as a thin deposit in the lee of boulders, or at the base of a few dwarf shrubs. You may have to obtain soil from underneath a clump of grasses or shrubs, or from underneath the lichen. Note if soils taken from underneath vegetation. Note depth of roots.

**Shipment:**

Ship samples, packed with ice packs, to:

Enviro-Test Laboratories  
9936 67 Ave  
Edmonton, AB  
T6E 0P5

Include DeBeers chain of custody form.

\*\* Laboratory Methods employed follow in-house procedures, which are generally based on nationally or internationally accepted methodologies.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
ED	Enviro-Test Laboratories - Edmonton, Alberta, Canada	SK	Enviro-Test Laboratories - Saskatoon, Saskatchewan, Canada

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

UNLESS OTHERWISE STATED, SAMPLES ARE NOT CORRECTED FOR CLIENT FIELD BLANKS.

Although test results are generated under strict QA/QC protocols, any unsigned test reports, faxes, or emails are considered preliminary.

Enviro-Test Laboratories has an extensive QA/QC program where all analytical data reported is analyzed using approved referenced procedures followed by checks and reviews by senior managers and quality assurance personnel. However, since the results are obtained from chemical measurements and thus cannot be guaranteed, Enviro-Test Laboratories assumes no liability for the use or interpretation of the results.

# ENVIRO-TEST QC REPORT

Page 39 of 39

Workorder # L76761

## Legend:

Limit	95% Confidence Interval (Laboratory Warning Limits)
DUP	Duplicate
RPD	Relative Percent Difference ((higher result-lower result)/Average, expressed as %)
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Materials
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material

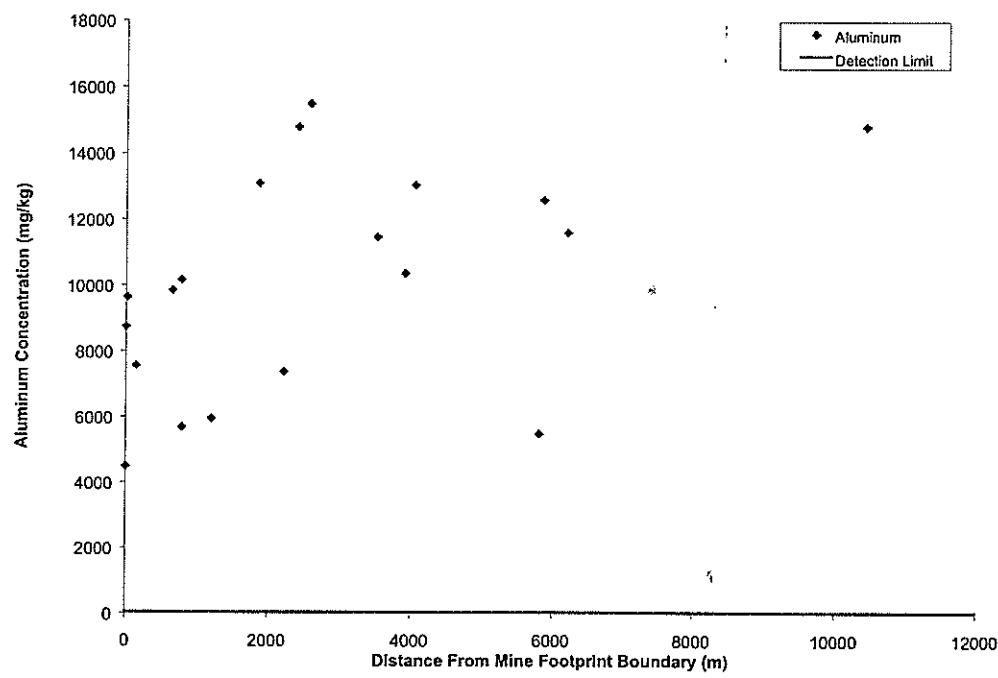

## Qualifier:

RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.
A	Method blank exceeds acceptance limit. Blank correction applied, where appropriate.
B	Method blank result exceeds acceptance limit, however, it is less than 5% of sample concentration. Blank correction not applied.
D	Duplicate result may exceed limit due to increased variability for low level samples.
E	Matrix spike recovery may fall outside the acceptance limits due to high sample background.
F	Silver recovery low, likely due to elevated chloride levels in sample.
G	Outlier - No assignable cause for nonconformity has been determined.
H	Result falls within the 99% Confidence Interval (Laboratory Control Limits)
J	Duplicate results and limit(s) are expressed in terms of absolute difference.

**APPENDIX V**  
**LICHEN AND VASCULAR PLANT DATA**

**Table V-1    Average Concentrations of Metals and Polycyclic Aromatic Hydrocarbons in Lichen at Random Sample Locations, August 2002**

Parameter	Detection Limits (mg/kg)	Average Concentration (mg/kg dry weight)	Standard Deviation
<b>Metals</b>			
Aluminum	4	650	396
Antimony	0.04	0.04	(all values are at or less than detection limit)
Arsenic	0.2	0.4	0.1
Barium	0.1	57	19
Beryllium	0.2	0.2	(all values are at or less than detection limit)
Cadmium	0.08	0.1	0.01
Calcium	10	2,385	564
Chromium	0.2	7.7	8.7
Cobalt	0.08	0.5	0.2
Copper	0.08	3.2	0.7
Iron	2	835	665
Lead	0.04	1.4	0.4
Magnesium	2	558	151
Manganese	0.04	132	55
Mercury	0.01	0.07	0.02
Molybdenum	0.04	0.20	0.08
Nickel	0.08	19	20
Phosphorous	2	598	113
Potassium	2	939	120
Selenium	0.2	0.3	0.07
Silver	0.08	0.08	(all values are at or less than detection limit)
Sodium	2	80	23
Strontium	0.04	12	5
Thallium	0.04	0.04	(all values are at or less than detection limit)
Tin	0.08	0.1	0.04
Titanium	0.1	32.5	28
Vanadium	0.08	1.7	1.3
Zinc	0.2	36	6.6
<b>PAHs</b>			
Benzo(a)anthracene	0.01	<0.01	(all values are less than detection limit)
Benzo(a)pyrene	0.01	<0.01	
Benzo(b)fluoranthene	0.01	<0.01	
Benzo(k)fluoranthene	0.01	<0.01	
Dibenzo(a,h)anthracene	0.01	<0.01	
Indeno(1,2,3-cd)pyrene	0.01	<0.01	
Naphthalene	0.01	0.02	0.01
Phenanthrene	0.01	0.01	0.01
Pyrene	0.01	<0.01	(all values are less than detection limit)
Quinoline	0.01	<0.01	

**Table V-2      Average Concentrations of Metals and Polycyclic Aromatic Hydrocarbons in Vascular Plants at Random Sample Locations, August 2002**

Parameter	Detection Limits	Average Concentration	Standard Deviation
<b>Metals</b>			
Aluminum	4	120	82
Antimony	0.04	0.04	(all values are at or less than detection limit)
