Note: Text is contained in Volume 1

Figures are contained in Volume 2

Tables and Appendices are contained in Volume 3.

## List of Contents

1. INTRODUCTION.....	1.1
Scope of study and report.....	1.1
Earlier studies.....	1.2
Diagenesis and ore-deposition models.....	1.5
Dolomitization and Presqu'ilization.....	1.5
Ore deposition.....	1.6
Dedolomitization.....	1.11
Sequence of diagenetic events.....	1.12
Methodology.....	1.13
Sources of data.....	1.13
Methodology and data processing.....	1.14
Representativeness of borehole data.....	1.19
2. PRINCIPLES OF REGIONAL GROUNDWATER FLOW.....	2.1
Background.....	2.1
Hydraulic time lag.....	2.4
Importance of postulate.....	2.4
Field results and their interpretation.....	2.4
Statement of problem.....	2.6
Method of computer calculation.....	2.7
Permeability of confining sequence $D_A + D_{II} + D_B$ .....	2.7
Sensitivity analysis.....	2.9
Validity of lag postulate.....	2.10
3. FRAMEWORK FOR GROUNDWATER FLOW IN STUDY AREA.....	3.1
Topography.....	3.1
Climate	
Geology.....	3.1
Subsurface information.....	3.1
Surficial geology.....	3.2
Overburden.....	3.2
Bedrock stratigraphy.....	3.3
Tectonics.....	3.4
Presqu'ile dolomite.....	3.7
Subsurface dissolution of evaporites.....	3.8
Subsurface dissolution of salt beds.....	3.8
Occurrence of salt in the study area.....	3.8
Dissolution of salt in the Prairie provinces.....	3.9
Dissolution of salt beds in the Upper Mackenzie	
River area.....	3.11
Dissolution of salt beds in the Pine Point area.....	3.12
Subsurface dissolution of carbonates and sulphates.....	3.13
Glacial effects.....	3.14
Glacial erosion and sediments.....	3.14
Groundwater recharge through glaciers and ice sheets.....	3.19
Chemistry of groundwater in former 'subglacial' rocks	
of the Canadian Shield.....	3.22
Isostatic rebound and water levels of glacial	
Great Slave Lake (Lake McConnell).....	3.27

<b>Karst development, collapse and some associated</b>	
diagenetic changes.....	3.28
Background.....	3.28
Karst features near orebodies.....	3.29
'Normal', interconnected tabular and prismatic 'karsting'..	3.29
Internal sediments.....	3.31
'Isolated' prismatic karst features.....	3.32
'Anomalous', unconsolidated collapse features.....	3.32
An unconsolidated prismatic collapse orebody: A-55.....	3.34
Geological setting.....	3.34
Collapse structure.....	3.35
Alteration.....	3.36
Ore geology.....	3.37
Groundwater flow.....	3.39
A tabular orebody: L-37.....	3.40
Geological setting.....	3.40
Ore geology.....	3.40
Development of karst in the Pine Point area.....	3.44
Background.....	3.44
Karst development processes and their age.....	3.44
Devonian (?) paleokarst.....	3.45
Post-jurassic karst development.....	3.45
Pleistocene karst development.....	3.46
Hydrodynamic blowout: a mechanism for 'catastrophic'	
creation and rejuvenation of karstic features by the	
Laurentide Ice Sheet.....	3.47
Lateral and vertical extend of karst development.....	3.49
Background.....	3.49
Interpretation of borehole data collected.....	3.49
 4. REGIONAL GROUNDWATER FLOW.....	4.1
Regional hydrodynamics.....	4.1
Background.....	4.1
Occurrence of artesian flow from boreholes.....	4.1
Rate of discharge and implied hydrodynamic gradients.....	4.2
Depth of active groundwater flow.....	4.4
Interaction between groundwater and surface water flow.....	4.5
Distribution of recharge and discharge areas.....	4.7
Regional hydrochemistry.....	4.8
Background.....	4.8
Chemistry of groundwaters.....	4.9
Major ion chemistry.....	4.9
Sulphur and hydrogen isotopes.....	4.11
Chemistry of surface waters.....	4.15
Major ion chemistry.....	4.15
Isotope chemistry.....	4.16
Permeability of rocks.....	4.17
Background.....	4.17
Measurement of permeabilities.....	4.17
Permeability of Middle Devonian carbonates.....	4.18
Field values reported for the Pine Point Barrier.....	4.18
Permeability of vugs.....	4.18
Intergranular permeability of carbonates.....	4.19

### III

Permeability of anhydrite and gypsum layers.....	4.19
Karstic systems.....	4.19
Open fractures within anhydrite layers.....	4.20
Permeability of salt dissolution breccia, granite wash and basement rocks.....	4.22
 5. GROUNDWATER FLOW NEAR OREBODIES IN THE PINE POINT DISTRICT....	5.1
Background.....	5.1
Hydrochemical observations at orebodies.....	5.2
Background.....	5.2
Normal interconnected tabular and prismatic orebodies..	5.2
Isolated prismatic orebodies.....	5.4
Anomalous prismatic orebodies.....	5.4
Structural conclusions from hydrochemical observations.....	5.7
Ion and sulphur isotope chemistry of 'black' water.....	5.7
Biochemical processes.....	5.8
Background.....	5.8
Biochemical processes in dewatering channels at open pits.....	5.9
Changes in bacterial population and chemistry during the K-77 pump test (1980).....	5.10
Return-flow from dewatering ditches at open pits at Pine Point.....	5.11
Comparison of premining vs. mining situation.....	5.12
Background.....	5.12
Changes near open pits.....	5.13
Regional effects.....	5.13
Effects at karst springs.....	5.13
Observations from the occurrence of saline water....	5.16
Changes of flow at artesian boreholes.....	5.17
Conclusions.....	5.18
 6. DIAGENETIC CHANGES AND THEIR INTERACTION WITH GROUNDWATER FLOW.....	6.1
Diagenetic changes in carbonates.....	6.1
Development of porosity.....	6.1
Ore genesis.....	6.2
Diagenetic changes in non-carbonate rocks.....	6.4
 7. REDUCTION OF PUMPING REQUIREMENTS.....	7.1
Economic and environmental considerations.....	7.1
Karst water problems in subsurface lignite mines in Hungary.....	7.2
'Active' and 'passive' dewatering methods.....	7.4
Sand and gravel injection technology.....	7.5
Success rate of passive dewatering in Hungarian mines.....	7.6
Conditions for the use of the sand-gravel injection method in the Pine Point area.....	7.6

#### IV

8.	CONCLUSIONS.....	8.1
	Diagenesis, karst development and dolomitization.....	8.1
	Groundwater flow and chemistry.....	8.2
	Effects of mine dewatering and recommendations.....	8.3
9.	REFERENCES.....	9.1

## List of Figures

### Chapter 1

- Figure 1-1** Regional hydraulic-head distribution, Western Canada Sedimentary Basin, slice + 1000 to -1250 ft. (Datum: M.S.L.). Caribou Mountains stand out as a major regional recharge area (modified after Hitchon, 1969a, Fig. 5).

### Chapter 2

- Figure 2-1** Approximate flow pattern in uniformly permeable material between the sources distributed over the air-water interface and the valley sinks (figure and caption from Hubbert, 1940, Fig. 45).
- Figure 2-2** Schematic sketch of the head changes along an assumed flow line from a recharge area (hill) to a discharge area (valley). Flowing conditions occur at (4), although no artesian aquifer is present (from Weyer, 1978, Fig. 6).
- Figure 2-3** Schematic cross-section showing a confined aquifer of limited extent. Recharge is through an aquitard.
- Figure 2-4** General case of an artesian aquifer without outcrop. The topography is reflected in the head distribution in the

## LIST OF TABLES FOR CLIMATE

- 3.1. Climatological stations south of Great Slave Lake (Data from Atmospheric Environment Service: Climatological station data catalogue).
- 3.2. Normal precipitation, temperatures and extreme temperatures for climatological stations south of Great Slave Lake (Data from Atmospheric Environment Service: Canadian climate normals, 1951-1980, Temperature and precipitation; a; Prairie Provinces; b. The North - Y.T. and N.W.T.; and from computer files of the Atmospheric Environment Service)
- 3.3. Monthly, annual and normal precipitation records and indices (1975 to 1982 calendar years) for the climatological stations
  - A. Fort Smith Airport
  - B. Hay River Airport
  - C. High Level Airport
  - D. Fort Resolution Airport
  - E. Hay River Paradise Gardens
  - F. Pine Point(Data from Atmospheric Environment Service: 1975-1976 Monthly Record, Meteorological Observations in Canada;  
1976-1982 - Monthly Record, Meteorological Observations in Northern Canada  
- Monthly Record, Meteorological Observations in Western Canada, and from computer files of Atmospheric Environment Service)
- 3.4. Annual precipitation (1975-1982) in mm and in percentage of normal at Fort Smith Airport, Hay River Airport and High Level Airport for
  - A. calendar year
  - B. water year (October 1 - September 30)
- 3.5. Monthly snowfall and equivalent water contents (w.e.) for the winters from 1975 to 1982 for the stations
  - A. Fort Smith Airport
  - B. Hay River Airport
  - C. High Level Airport
- 3.6. 1975-1982 snow depths at end of month and deviation from normal for stations
  - A. Fort Smith Airport
  - B. Hay River Airport
  - C. High Level Airport
- 3.7. Annual precipitation in percentage of 1951-1980 normals at Fort Smith Airport, Hay River Airport and High Level Airport for calendar years (A) and water years (B).

*Handwritten notes:*  
From the report of 1965-1966 for the  
Fort Smith and Hay River  
(also for the 1967-1968 period)

- 3.8. Deviation (in %) of annual precipitation from 1951 to 1980 normal at Fort Smith Airport, Hay River Airport and High Level Airport for calendar years (A) and water years (B).
- 3.9. Symbolic classification table for deviations of precipitation from 1951-1980 normal at Fort Smith Airport, Hay River Airport and High Level Airport for calendar years (A) and water years (B).

2nd Table ...  
1945-1980

3rd Table ...

3.1 Minimum and maximum daily precipitation  
(1945-1980) of Fort Smith Airport and Hay River Airport  
(1945-1980 : 075 8301) and Fort Smith Airport  
(1945-1980 : 075 8301). Data from 1945.

TABLE FOR LAKE LEVEL FLUCTUATIONS OF GREAT SLAVE LAKE

2. 4. Minimum and maximum daily gage heights (1970-82) of  
Great Slave Lake in Yellowknife Bay (WSC - station:  
075B001) and Fort Resolution (WSC - station: 07B001).  
Data from Water Survey of Canada, Yellowknife office.

## TABLES FOR DISCHARGE IN RIVERS SOUTH OF GREAT SLAVE LAKE.

3-12 ~~1~~. 1975-1982 monthly summary of daily discharges [ $\text{m}^3/\text{s}$ ] at gaging stations at the rivers.

- A. Buffalo River (WSC - station No. 07PA001)
- B. Little Buffalo River (WSC - station No. 07PB002) and
- C. Hay River (WSC - station No. 07B001)

Data from Water Survey of Canada, Yellowknife office.

3-13 ~~2~~. Annual discharges and related total precipitations 1975-1982 for the rivers

- A. Buffalo River (WSC - station No. 07PA001)
- B. Little Buffalo River (WSC - station No. 07PB002)
- C. Hay River (WSC - station No. 07B001)

aquifer. Flow in the aquifer is from highlands to lowlands.

**Figure 2-5** Schematic cross-section showing confined aquifer extending under a lake. Recharge through aquitard.

**Figure 2-6** Conventional model of artesian systems. Recharge at outcrop of artesian aquifer only. 1: artesian aquifer, 2: confining layer, A: piezometric level (head) of aquifer below topographic surface, B: piezometric level of aquifer above topographic surface - artesian (flowing) borehole.

*Figure 2-7  
2-8*

**Figure 2-7** Stratigraphy of the Red Earth region and schematic relationship of topography and piezometric surfaces in the Devonian aquifers D<sub>I</sub> and D<sub>II</sub>. Stratigraphy modified after Tóth (1978, Fig. 3).

### Chapter 3

**Figure 3-1** Geographical and topographical features south of Great Slave Lake. BL = Buffalo Lake; BR = Buffalo River; FS = Fort Smith; FR = Fort Resolution; HC = Hanbury Creek; HP = High Point; HR = Hay River (river and town); JR = Jackfish River; KL = Kakisa Lake; KR = Kakisa River; LBR = Little Buffalo River; MR = Mackenzie River; NR = Nyarling River; PP = Pine Point; PR = Peace River; SB = Sulphur Bay; SLR = Slave River; SP = Sulphur Point; SR = Salt River; TL = Tathlina Lake; YK = Yellowknife.

**Figure 3-2** A. Mineral and hydrocarbon exploration holes adjacent to Great Slave Lake.

## VII

### B. Location of boreholes included in geologic evaluation by computer.

- Figure 3-3** Oil wells evaluated for the study. For cross-section 1 to 3, see Fig. 4-3. BM = Birch Mountains; CH = Cameron Hills; CM = Caribou Mountains; EL = Escarpment Lake No. 1, No. 2 and No. 3; F = Hay River Test No. 1, No. 2, No. 3, No. 5b, No. 6, No. 8 (compare Fig. 4-2); WBNP = Wood Buffalo National Park; WP = Windy Point No. 1. Triangles = oil wells; full circles = discharge gaging stations; diamond = karst spring and borehole 104.
- Figure 3-4** Map of surficial geology of the area investigated (after Alberta Research Council, 1970; Douglas, 1974; Douglas and Norris, 1974). Qal = Quaternary; uD = Upper Devonian; mD = Middle Devonian; pC = Precambrian; HL = 'hinge line'; MDF = McDonald Fault; PF = Prebble Fault; PP = Pine Point.
- Figure 3-5** Thickness of glacial till in the Pine Point area (ft). Arrows indicate probable reflections of karstic and structural features of the Devonian bedrock.
- Figure 3-6** Stratigraphic correlation of Devonian Formations, Western Canada Sedimentary Basin (from Meijer-Drees and Davies, 1976).
- Figure 3-7** North-South cross-section, Horn Plateau, Great Slave Lake, Caribou Mountains, Peace River, foot of Birch Mountains (after Meijer-Drees and Davies, 1976). For position of cross-section and boreholes, see Fig. 3-19 (cross-section A).
- Figure 3-8** Phanerozoic stratigraphy and significant events in the Pine Point area (from Krebs, 1982, Fig. 11).

## VIII

- Figure 3-9** Geologic nomenclature adopted for the evaluation of borehole data by this report (modified after Skall, 1975).
- Figure 3-10** Schematic north-south cross-section through Middle Devonian, Pine Point property, N.W.T., showing some of the major orebodies (from west to east: A-70, Z-63-N, K-57, O-42, M-40, W-17, X-15, N-204). Letters in circles are facies-types identified by Skall (1975). From Macqueen and Powell (1983) after Skall (1975) and Kyle (1981).
- Figure 3-11** N-S and NE-SW fault zones in the Precambrian based on interpretation of large-scale geomagnetic maps (after Douglas, 1970, aeromagnetic map).
- Figure 3-12** Average orientation of vertical joint sets in host rocks of Pine Point open pits J-44, N-31, N-32, N-38A, N-42, O-32, O-42, P-29 and P-32 (after Kessler et al., 1972, Fig. 3).
- Figure 3-13** Elevation of top of E-shale, based on the evaluation of available exploration boreholes. Fault A in Fig. 3-13B is vertical displacement fault found by Abadena Oil.
- Figure 3-14** Elevation of top of Amco shale (ft), based on the evaluation of available exploration boreholes.
- Figure 3-15** Elevation of surface of Devonian rocks (ft), according to evaluation of available borehole logs.
- Figure 3-16** Isopach map of Presqu'ile Formation (modified after Vasquez, 1968, map 3).

- Figure 3-17** Occurrence of top of presqu'ilization in the Slave Point Formation (B), Watt Mountain Formation (C) and Pine Point Group (D); A is composite of B, C and D (triangle = SPF; circle = WM; cross = PPG). Presqu'ile in PPG extends south towards Wood Buffalo National Park.
- Figure 3-18** Occurrence of green waxy Watt Mountain shale in fractures, vugs and cavities under the Watt Mountain Formation (A) and in Presqu'ile dolomite (B).
- Figure 3-19** Occurrence of Lotsberg salt in the Upper Mackenzie River area (after Meijer-Drees and Davis, 1976). For cross-section A see Fig. 3-7; for cross-section B see Fig. 3-25.
- Figure 3-20** Occurrence of Cold Lake Salt in the Upper Mackenzie River area and Northern Alberta (after Meijer-Drees and Davies, 1976).
- Figure 3-21** Facies map of the Muskeg Formation and equivalent strata (from Meijer-Drees and Davies, 1976).
- Figure 3-22** Salt dissolution, East-central Alberta (after Hamilton, 1971).
- Figure 3-23** Dissolution of Cold Lake Salt NW of Great Slave Lake and associated collapse and brecciation (after N.C. Meijer-Drees, personal communication, 1982).
- Figure 3-24** Salt solution breccia from 540 ft depth in oil well Iskut Silver Little Buffalo K-22. Photo: B. C. Rutley, ISPG.

- Figure 3-25 Stratigraphic cross-section B-B', Great Slave Lake (Cominco G-4) to Wood Buffalo National Park (Iskut Little Buffalo K-22) (modified after Rice, 1967, Fig. 4).
- Figure 3-26 Deformation of post-Cold Lake strata due to dissolution of Cold Lake salt (after Meijer-Drees and Davies, 1976).
- Figure 3-27 Solubility of gypsum in aqueous solutions in dependence of NaCl concentrations and temperature. A: from van Everdingen (1970, Fig. 1; example only, not to be used for actual determinations), B: after Shternina (1960).
- Figure 3-28 Diagrams of  $Mg^{2+}$ ,  $Ca^{2+}$  and  $HCO_3^-$  concentrations versus  $Cl^-$  concentrations of 593 water samples collected south of Great Slave Lake, 1978-1980.
- Figure 3-29 A. Occurrence of igneous rocks, gneiss and carbonate pebbles in unconsolidated layers directly above the Paleozoic rock.  
B. Occurrence of igneous rocks in sinkholes and within orebody A-55.
- Figure 3-30 Various sequences of basal thermal regime and associated erosional processes encountered beneath the Laurentide Ice Sheet at its maximum (from Sugden, 1977, Fig. 12).
- Figure 3-31 Morphology of the Laurentide Ice Sheet at its maximum (from Sugden, 1977, Fig. 2).
- Figure 3-32 Zones of contrasting basal thermal regime beneath the Laurentide Ice Sheet at its maximum (from Sugden, 1977, Fig. 11).
- Figure 3-33 Maximum western extent of glacial Great Slave Lake (after Craig, 1965, Fig. 2).

- Figure 3-34** Elevated beach lines of glacial and postglacial Great Slave Lake in the Buffalo River area (after McGregor, 1949, Fig. 1; isohypses from topographical map Buffalo Lake NTS 85B, Scale 1:250 000).
- Figure 3-35** Distribution of "normal" karst features in the Pine Point Barrier according to Rhodes (1982, Plate 8).
- Figure 3-36** Regional occurrence of unconsolidated internal sediments as extracted from available borehole logs. A = sand; B = mud in cavities, fractures or vugs (other than green waxy mud); C = black mud; D = green waxy mud below Watt Mountain Formation; E = erratics.
- Figure 3-37** Schematic diagram showing position of anomalous unconsolidated collapse orebodies within the Pine Point Barrier (after Rhodes, 1982, Plate 9).
- Figure 3-38** Major geological features and outline of orebody on 4th and 14th bench (after Alldrick, 1982, Figs. 2 and 3). Cross-section is shown in Fig. 3-39.
- Figure 3-39** Geologic cross-section through the A-55 orebody. Location of cross-section is shown on Figure 3-38 (after Alldrick, 1982, Fig. 4).
- Figure 3-40** Temporary rebound of water level in well hole 7, A-55 pump test, December 1979 (from Weyer 1981b; source of data: Pine Point Mines Ltd.).
- Figure 3-41** Longitudinal NE-SW cross-section through the tabular orebody L-37 showing Pleistocene sinkhole and spatially associated sulphide precipitation (after Webb, 1982).

## XII

**Figure 3-42** Hypothetical groundwater flow system at the time of initiation of the Howe Lake structure (modified after Christiansen et al., 1982, Fig. 14).

**Figure 3-43** Occurrence of formations in boreholes evaluated. A = overburden with reported depth; B = Hay River Formation; C = Slave Point Formation; D = Watt Mountain Formation; E = Pine Point Group; F = Lower Keg River Formation; G = Chinchaga Formation; H = Mirage Point Formation; I = Precambrian (open square = not certain).

**Figure 3-44** Occurrence of open and infilled cavity systems in Devonian Formation of the Pine Point area, based on the evaluation of available borehole logs and drilling records. A = all formations; B = Hay River Formation (open squares = erratics in Hay River shale); C = Slave Point Formation; D = Watt Mountain Formation; PPG = Pine Point Group; LA = Lower Keg River Formation; CH = Chinchaga Formation.

**Figure 3-45** Overall occurrence of collapse structures, breccia and sinkholes, according to the evaluation of available borehole logs. A = composite; B = collapse structures; C = breccia; D = sinkholes (more than 100 sinkholes were not listed due to time restrictions imposed by management).

**Figure 3-46** Occurrence of brecciation in individual formations according to the evaluation of available borehole logs. A = all formations; B = Hay River Formation; C = Slave Point Formation; D = Watt Mountain Formation; E = Pine Point Group; F = Lower Key River Formation; G = Chinchaga Formation.

### XIII

- Figure 3-47** Occurrence of vugs according to the evaluation of available borehole logs. A = all formations; B = Slave Point Formation; C = Watt Mountain Formation; D = Pine Point Group; E = Lower Keg River Formation; F = Chinchaga Formation.
- Figure 3-48** Occurrence of spongy (A), very vuggy (B) and pin point porosity (C) structures as well as completely filled vugs (D), according to evaluation of available borehole logs.
- Figure 3-49** Occurrence of broken and badly broken rocks, according to evaluation of available borehole logs. A = all formations; B = Hay River Formation; C = Slave Point Formation; D = Watt Mountain Formation; E = Pine Point Group; F = Lower Keg River Formation; G = Chinchaga Formation.
- Figure 3-50** Locations of orebodies (squares) and mineral showings (crosses; > 1% metal contents) according to evaluation of available borehole logs and other sources available to us.
- Figure 3-51** Occurrence of sphalerite and galena according to evaluation of borehole logs. A = all formations (triangle = sphalerite; square = galena; cross = both); B = overburden; C = Hay River Formation; D = Slave Point Formation; E = Watt Mountain Formation; F = Pine Point Group; G = Lower Keg River Formation.
- Figure 3-52** Occurrence of elemental sulphur (A-F) and massive amounts of  $H_2S$  (G) according to evaluation of available borehole logs. A = all formations; B = Hay River

Formation; C = Slave Point Formation; D = Watt Mountain Formation; E = Pine Point Group; F = Lower Keg River Formation; G = occurrence of massive amounts of  $H_2S$ .

Figure 3-53 Occurrences of hydrocarbons according to evaluation of available borehole logs. A = bitumen and tar; B = oil; C = bitumen and oil stain; D = methane ( $CH_4$ ).

Figure 3-54 Occurrence of oil in individual formations of the Pine Point area according to evaluation of available borehole logs. A = all formations; B = Hay River Formation; C = Slave Point Formation; D = Watt Mountain Formation; E = Pine Point Group; F = Lower Keg River Formation.

Figure 3-55 Occurrence of bitumen and tar in individual formations of the Pine Point area according to evaluation of available borehole logs. A = all formations; B = Hay River Formation; C = Slave Point Formation; D = Watt Mountain Formation; E = Pine Point Group; F = Lower Keg River Formation.

#### Chapter 4

Figure 4-1 A. Occurrence of artesian conditions in boreholes on Great Slave Lake and in adjacent discharge areas south of the lake, as reported in the available borehole files.  
B. Cessation of flow from artesian boreholes and karst springs (stars for both) since commencement of dewatering at Pine Point Mines.

- Figure 4-2** Detailed location and surface elevation (in feet) of oil wells Hay River Test 1, 2, 3, 5B, 6 and 8. Location of wells from a map by Frobisher Exploration Company (1946); elevation data from D. Adams (1982, personal communication).
- Figure 4-3** North-south cross-section from oil well Windy Point No. 1 to Alexandra Falls B-07 showing the occurrence of artesian flow conditions below the Chinchaga evaporites (modified after K. Williams, 1982, personal communication). Compare Fig. 3-3 for position of cross-section.
- Figure 4-4** Results of discharge measurements in  $\text{m}^3/\text{s}$  taken along the Buffalo River, Hanbury Creek, Little Buffalo River, Nyarling River and Salt River (modified after Weyer et al., 1979, Fig. 4).
- Figure 4-5** Buffalo River: stretches without bridging ice cover, November 30, 1975 (modified after Weyer, 1975, Fig. 1).
- Figure 4-6** Reef facies underlying Watt Mountain Formation near Buffalo River (modified after Wiley, 1970, Fig. 5).
- Figure 4-7** Natural sulphur spring discharging at left bank of Buffalo River, downstream of highway bridge (from Weyer, 1978b, Fig. 5).
- Figure 4-8** Belts of regional discharge areas of sulphurous and saline/sulphurous groundwater along Little Buffalo River and Salt River. Mapped from a Landsat 1 image (August 27, 1973; E-1400-181600-6; bands 5, 6 and 7; chemistry determined by selected ground control).

- Figure 4-9      Locations of water samples collected south and west of Great Slave Lake.
- Figure 4-10     Semilog plot of chemical characteristics of selected water samples (from Weyer et al., 1979, Fig. 3; EPM = equivalent per million).
- Figure 4-11     Occurrence of chloride ions in surface waters and discharging groundwaters. A belt of discharging saline water occurs in the lowlands along Salt River, Little Buffalo River, Great Slave Lake and Hay River. Compare Fig. 4-8.
- Figure 4-12     Occurrence of sulphate ions in surface waters and discharging groundwaters. A belt of discharging sulphurous water occurs parallel to the belt of saline/sulphurous water in the lowlands along Salt River, Little Buffalo River, Great Slave Lake and Hay River. Compare Fig. 4-8.
- Figure 4-13     Occurrence of calcium ions in surface waters and discharging groundwaters. Similar groundwater discharge patterns are indicated as in Figs. 4-8, 4-11 and 4-12.
- Figure 4-14     Occurrence of chloride in deep groundwater taken from oil wells; data extracted from Table 1.3.
- Figure 4-15     Occurrence of  $\text{SO}_4^{2-}$ ; deep groundwater taken from oil wells; data extracted from Table 1.3.
- Figure 4-16     A. Distribution of measured  $\delta^{34}\text{S}$  values for dissolved sulphate and sulphide.  
B. Distribution of corrected  $\delta^{34}\text{S}$  values for dissolved sulphur species. In areas with horizontal

stripes, isotopic balances were calculated from measured  $\delta^{34}\text{S}$  values and concentrations of sulphate and sulphide ions. In areas without stripes, measured  $\delta^{34}\text{S}$  values for sulphates only were used, since sulphide data were lacking.

Figure 4-17 Scatter diagrams of  $\delta^{34}\text{S}$  in  $\text{SO}_4^{2-}$  versus sulphate concentrations in natural waters south of Great Slave Lake. The numbers 26 and 50 signify 26 or 50 data points not plotted in the area of the number.

A. Using measured distribution of  $\delta^{34}\text{S}$  in dissolved sulphate.

B. Using corrected  $\delta^{34}\text{S}$  values, after the isotopic balance and the initial  $\text{SO}_4^{2-}$  content had been calculated using  $\text{H}_2\text{S}$  values.

Figure 4-18 Population of  $^2\text{H}$  isotopes in water samples and comparison of  $\text{Cl}^-$  concentration (A) and topographic elevation (B).

Figure 4-19 Occurrence of lighter  $^2\text{H}$  values ( $< -1650/00$ ; group 2) in surface waters and discharging groundwaters. Similar groundwater discharge pattern are indicated as in Figs. 4-8, 4-11, 4-12 and 4-13.

ACKNOWLEDGEMENTS

This report results from a Joint Research Project between Pine Point Mines Ltd. and the Federal Department of Environment. The project was proposed by the late W. H. Gibney, Manager of Pine Point Mines. J. P. Bruce, N. H. James, the late E. R. Peterson and D. H. Lennox implemented and supported the project within the Inland Waters Directorate of the Federal Department of Environment.

Much support was received from Mr. K. J. Durston, chief engineer of Pine Point Mines. Early discussions with Mr. P. Santos, D. Adams, K. Newman, H. Skall and S. Hoffmann of Pine Point Mines and Cominco Ltd. were particularly useful. Discussions were also held with N. Zarkos, J. Collins, K. Carter, R. Armstrong and T. Healy of Pine Point Mines. All their contributions are gratefully acknowledged. D. Adams, Cominco Ltd., Calgary, cooperated in core investigations at the Institute of Sedimentary and Petroleum Geology (ISPG) and provided valuable advice regarding stratigraphic and sedimentological matters.

D. Hocking, Canadian Forestry Service, first confronted me with groundwater flow south of Great Slave Lake. The Water Survey of Canada (G. Morton, K. Davies) made the facilities and services of the Fort Smith Office (A. Wilson, D. Dube, T. Wilson) available to us. Part of our chemical analyses were provided by the Water Quality Branch, Calgary (M. Korchinsky). Microbiological studies were done by the Environmental Protection Service, Edmonton (J. Bell, G. Elliott, F. Zaal). Parks Canada, Winnipeg (J. Mathers) and Parks Canada, Ft. Smith (B. Liefs, A. Starko) provided permission to install a discharge gaging station in Wood Buffalo National Park.

Within the National Research Institute, I worked closely together with Mrs. W. C. Horwood-Brown. Much help was also received from J. A. Banner, R. O. van Everdingen and E. Pearn. G. Hint, R. Gardiner and J. Ruitenbeek temporarily worked as students within the research project.

The stable isotope facilities at the University of Calgary (H. R. Krouse, M. A. Shakur) received financial support for this study from the Natural Sciences and Engineering Research Council of Canada. Technical assistance was provided by L. Boreiko, J. Pontoy and N. Lozano.

A. G. Redshaw, R. Hale and the Water Resources Division of DIAND, Yellowknife, assisted in data collection. D. Graham, Northwest Territories Forestry Service, DIAND, Ft. Smith, often released helicopters for our use during forest fire seasons. Most of the borehole data and valuable discussions were provided by W. Padgham and W. Gibbons, DIAND, Yellowknife and D. D. Brown, DIAND, Ottawa.

Borehole data were also made available by Westmin Resources (A. Soregaroli, A. Rendall).

The many contributions from the Geological Survey of Canada (EMR) are appreciated. Several geologic aspects of the study were discussed with H. Geldsetzer, O. Hughes, L. Jackson, N. Meijer-Drees, D. Morrow, T. Powell, D. Sangster and K. Williams. A. E. Foscolos, J. Wong, A. Heinrich, O. McEwan, W. Kalkreuth, K. Pratt and G. P. Michael analysed various rock samples. The core-storage facility of the ISPG (W. J. Banning) made boreholes files and cores available for inspection. Photographs of cores from oilwells Iskut Little Buffalo K-22 were prepared by B. C. Rutley and W. B. Sharman. Library service was received from the ISPG (M. Jones) and from the Gallenger and main library of the University of Calgary. R. McQueen (ISPG and University of Waterloo) made a prepublication copy of paper by Krebs available.

In an early stage of the investigation K. Werner of the Geological Survey of N.W., Krefeld, Germany, analysed mineral precipitates in discharge channels.

The Department of Public Works of the NWT provided accommodation in Pine Point during the first two years.

We would like to thank all the many individuals who have contributed to the success of this study. Parts or all of the manuscript have been read by R. O. van Everdingen, H. Geldsetzer and G. Holdsworth who also provided comments. Thanks are due to E. Pearn, S. Diocee and D. Petrunia for typing the manuscript, to W. C. Horwood-Brown and U. von der Dick for drafting part of the figures, to W. C. Horwood-Brown and J. Ruitenbeek for computer data processing and last not least to W. Weyer for proofreading and organisational help.

## 1. INTRODUCTION

### SCOPE OF STUDY AND REPORT

This paper describes an investigation of groundwater flow, water chemistry, porosity and permeability distribution and their relationship to salt dissolution, karstification and glacial events on a regional and local scale in the area of Pine Point, N.W.T., a by now famous Canadian lead-zinc deposit of the Mississippi-Valley type.

During spring of 1976, difficulties had been encountered in achieving the dewatering goals at open pits of Pine Point Mines, in particular at the open pit R-61 as had been predicted by the Hydrology Research Division (HRD; K. U. Weyer) during a visit in November, 1975.

In July 1976, W. H. Gibney, Manager, Pine Point Mines Ltd., proposed a joint research study to the Hydrology Research Division (D. H. Lennox, Chief) of Environment Canada<sup>1)</sup> to investigate the mechanisms of groundwater flow in the Pine Point region and their effect on the dewatering of the Pine Point ore bodies.

It was agreed that Pine Point Mines would carry the operational costs while HRD/NHRI provided mantime and office space for the joint research project. Because of federal constraint programs Pine Point Mines, at a later stage, also carried some of the personnel costs. The joint research project was terminated at the end of 1981. Since then all costs have been carried by NHRI.

Hydrogeologic field studies and data processing commenced in 1977 and continued until 1981, intermittently, because of inherent circumstances. Finally, limitations of resources and the time-consuming collection of geologic data during 1982 restricted not only the time available for actual preparation of this report but also thereby its scope.

1) The groundwater section of HRD is now the Ground Water Division, National Hydrology Research Institute (NHRI) of the federal Department of Environment (Environment Canada).

### EARLIER STUDIES

Groundwater flow in northeastern Alberta and adjacent parts of the Northwest Territories has been dealt with in a number of papers, notably those of Cameron (1917), Camsell (1917), Brandon (1965), Richmond (1965), Hitchon (1969a, 1969b, 1971), and Hitchon et al. (1969). Davidson (1967a, b), Billings et al. (1969) and Kesler et al. (1972) refer to groundwater flow conditions at the time of ore genesis.

Major springs were observed along the south shore of Great Slave Lake from Little Buffalo River to Sulphur Point (see Fig. 3-1 for geographic locations), and along the north-west shore from Windy Point to Sulphur Bay by Cameron (1917). The springs close to Little Buffalo River were salty-tasting while sulphur dominance was reported for a "very large spring" on the west side of Sulphur Point and for "large sulphur springs" (accompanied by numerous seepages of petroleum) in the vicinity of Windy Point (ibid). "Strongly flowing sulphur springs" were abundant at Sulphur Bay (ibid.). At Slave Point, close to Windy Point, "a small sulphur spring was noted and the interior of the point contains a large, open gravel and clay area, apparently the basin of a large alkaline sulphur spring now dried up. Large quantities of decayed and salt-encrusted timber are scattered about this area, many pieces having the yellowish tinge of sulphur" (Cameron, 1917, p. 73). With regard to dolomitization and petroleum occurrence at Windy Point, Cameron (1917) suspected the following process at work: "The sulphur-bearing waters rising from below carry considerable quantities of calcium and magnesium salts and percolating through the overlying thin bedded limestones change them to crystalline magnesian limestones and dolomites. In the process the bitumen is set free and forced either into the cavities formed in the dolomites or through the fissures, developed during dolomitization, to the surface to form the tar and oil pools."

Camsell's (1917) chemical analysis of water from a spring discharging "about two gallons per minute" (0.15 l/s) on August 14, 1916, at Sulphur

Point is listed in Table 1.1, as well as analyses by Brandon (1965) taken at Sulphur Point on July 26, 1960, and at High Point on July 27, 1960.

Camsell's water sampling was motivated by "the possibility of finding salts of potassium associated with the gypsum beds of this region" (Camsell, 1917, p. 142). More samples were taken by Camsell in the regions east and south of the Caribou Mountains. None of the waters analyzed contained an unusual proportion of potash and it was concluded that potash was not present in commercial quantities in the vicinity of the points where samples were collected.

Richmond (1965) collected water samples from five springs and six sinkholes south of Great Slave Lake east of Copp and Needle Lake "in an attempt to detect updip flow of saline connate water from subsurface" (ibid., p. 231). The springs were at the base of a small scarp that marks the eastern edge of carbonate exposure. Chloride concentrations were found negligible and "seepage of connate water and solution of bedded halite are considered to be non-existent" (ibid., p. 232). Down-dip flow of groundwater was assumed (ibid., p. 236). The down-dip direction would be in an approximate south-westerly direction.

Brandon (1965) reported 420 mg/l chloride from a water sample taken in August 1961 at the mouth of the Buffalo River. Based on the results of a two dimensional cross-sectional electric analog model he postulated flow from Buffalo Lake through lower Devonian layers in an easterly direction toward the Little Buffalo River.

Hitchon (1969a, b, 1971) concluded from the analysis of fresh-water heads in oil wells that groundwater in Alberta is, in general, flowing from the Rocky Mountain and Foothills belt in a NE direction towards the edge of the Western Canada Sedimentary Basin. "Despite significant differences in geology from one part of the basin to another, the dominant fluid potential in any part of the basin corresponds closely to the fluid potential at the topographic surface in that part of the basin" (Hitchon 1969a, p. 194).

---

Figure 1-1

---

Showing hydraulic-head distribution between the elevation +1000 ft to -1250 ft, Figure 1-1 of this report (ibid., Fig. 5) indicates recharge in the Caribou Mountains and radial groundwater flow away from the circular plateau of the Caribou Mountains.

In a later paper, Hitchon (1971, Fig. 5) gave the impression that flow in the deeper Keg River Formation underflows the Caribou Mountain system from SW to NE. The 1000 ft (305 m) hydraulic-head isoline shows that two rivers to the northwest and south of the Caribou Mountains act as major recipients for groundwater flow, the Hay River to the northwest and the Peace River to the south. Hitchon et al. (1969a) suggested that the chloride contents of the Slave River originate in groundwater containing dissolved Middle Devonian halite. K/Na ratios in brines discharging in springs near the Salt River are very low, suggesting an origin from dissolved halite (ibid., p. 1401).

At the time of ore genesis groundwater flow within the Pine Point reef structure is thought to have been from the west (Billings et al., 1969), in both directions along a path trending N50°E (Kesler et al., 1972) and in both directions along eastern and SE pathways (ibid.). Billings et al. (1969) base their deductions on a chemical and isotope comparison with the Rainbow oil field in northwestern Alberta. Kesler et al. (1972) base their conclusions on a study of asymmetrical growth of sphalerite and galena crystals from Pine Point ore bodies and vertical joint sets in open pits.

Davidson (1966) discusses the genetic relationship between ore deposits and evaporites. For the Pine Point region Davidson (1967 a, b) suggests the origin of lead and zinc from dissolving Elk Point salt to the south and hence implies groundwater flow from the south. This view is supported by Roedder (1968a).

## DIAGENESIS AND ORE-DEPOSITION MODELS

Early in the course of the investigation it was recognized that the present-day groundwater flow systems utilized the same or similar porosity systems of a karstic and tectonic nature as did probably the dolomitizing and the ore-forming fluids. At first glance, groundwater flow and biochemistry seemingly allow metal sulfides to be formed even today in the same area (Weyer, 1975, Weyer et al., 1979). Porosity development in the Pine Point area has been affected by both ore genesis and dolomitization. Thus some attention will be devoted to the possible and probable interaction between these processes and groundwater flow.

Several models have been proposed in the past for the genesis of Mississippi-Valley type lead-zinc deposits and for the spatially associated dolomitization.

### DOLOMITIZATION AND PRESQU'ILIZATION

Dolomitization is a diagenetic change of a calcium-carbonate system into a magnesium-calcium carbonate system; presqu'ilization is the often late diagenetic change to a coarse crystalline dolomite (Skall, 1975).

Morrow (1982b) differentiates seven major dolomitization models:

(1) in the *hypersaline basin and seepage reflux model*, seawater infiltrates into the bottom of lagoonal systems and at some later time seeps seaward again; (2) in the *burial compaction model*,  $Mg^{2+}$ -bearing compaction water is expelled into carbonate reef bodies, causing dolomitization; (3) (4) in the *coorong model* and *sabkha model*, groundwater fills ephemeral lagoonal lakes, precipitating dolomite mud and magnesite when the lakes evaporate in the summer; (5) the *mixed water or dilution model*, documented by Hanshaw et al. (1971), explains deep burial dolomitization under the influence of fresh groundwater extracting the  $Mg^{2+}$ -ions from marine sources (mixing of fresh with salt water); a modification of this model is the pene-contemporaneous dolomitization by shallow coastal fresh-water aquifers;

(6) *solution cannibalization* refers to the derivation of  $Mg^{2+}$  from the dissolution of magnesian calcite and reprecipitation of low-magnesium calcite; *pressure solution* along solution seams and stylolites has also been seen as a major cause of dolomitization; and (7) *tectonic or hydrothermal dolomite* cross cuts strata as a coarsely crystalline white sparry dolomite; it has been designated as tectonic or hydrothermal as it often occurs near known fault systems; these fault systems may be conduits for groundwater flow and therefore may provide additional amounts of  $Mg^{2+}$ -ions for enhanced dolomitization.

Common to nearly all of the above models is the assumption that seawater of recent or ancient nature, not necessarily salt water in general, is the important ingredient for the dolomitization (D. Morrow, oral communication, 1982).

At Pine Point, *presqu'illization* is commonly considered to have been caused in a reefal environment by reflux of brines (Skall, 1975). The reef is regarded as being highly permeable along its depositional strike, whereas the surrounding rocks towards the south, the north, and underneath are assumed to be practically impermeable (J. Collins, personal communication, 1981; K. Carter, personal communication, 1982). Movement of fluids is thought to be restricted to the reef and permeable rocks close by. Flow is supposed to be mainly in an approximate E-W direction along the main trend of the reef.

#### ORE DEPOSITION

Already several hundred years ago, miners in the famous Annaberg mining district of Europe suspected that water flowing in the subsurface controlled the presence and abundance of mineral accumulations (Agricola, 1556). About one hundred years ago it was recognized that fluids of magmatic and meteoric origin cause the accumulation of ore bodies (summarized in Dáubree, 1887).

Ore deposition models for Mississippi-Valley type (MVT) lead-zinc deposits have been summarized by Ohle (1959), Brown (1970), and more recently, by Anderson and Macqueen (1982). Various hypotheses involving syn-sedimentary, early diagenetic and epigenetic processes are all alive and well for the various types of sediment-hosted deposits and although certain genetic factors are reasonably clear for each type, the interrelation of these factors and their role in the overall process of basin evolution is still not clear in many respects (Anderson and Macqueen, 1982).

In North American opinion, the late diagenetic or epigenetic aspects prevail for MVT deposits whereas in Europe the syngenetic approach is emphasized, especially by the Amstutz-school in Heidelberg (Brown, 1970). In both views, the precipitation of ore from fluids is closely associated with permeable pathways, either mud channels (syngenetic view) or dissolution structures (diagenetic view; classical paper: Grogan, 1949). The later view seems much more reasonable to most long-term students of the situation in the Southern Illinois district (Brown 1970). Nevertheless, studies of the Amstutz-school in the same area showed that at least part of the ore showings could also be interpreted as being syngenetic (Brown, 1970).

Important for the purpose of this report is the common consensus regarding the association of ore genesis with permeable zones. Within these permeable system MVT ore deposits are simply unusually large representatives of an ubiquitous phenomenon: occurrence of sphalerite and galena are commonplace in carbonate successions (Anderson and Macqueen, 1982).

Individual mining districts may be distributed over hundred of square kilometres, arguing against strictly local sources for metals and sulphur (Anderson and Macqueen, 1982). According to the same authors, there is evidence that mineralization took place at relatively shallow depths, from perhaps a few hundred to about 1,000 m, under average

host-rock temperatures that are significantly less than 100-150°C, requiring either a heat source at shallow depth or migration of heated fluids from a deeper source (White, 1974).

Although early workers commonly suggested that deposits were located within carbonate reef masses, subsequent work on many deposits has demonstrated that actual reef-hosted deposits form a minority (Anderson and Macqueen, 1982). Deposits are closely controlled by the prior development of porosity, and thus may be located in platform carbonates of different character. At Pine Point, ore bodies are located in carbonates of biostromal character, in back-reef and in fore-reef setting (Skall, 1975).

Metal transport and deposition are explained by two basic models: the *basin brine hypothesis* assumes brine is flowing towards the deposit, continuously leaching metal-ions from various sedimentary strata along the flow path and releasing them at the site of the orebody. Jackson and Beales' (1967) model with shale-derived metals is a classical example of this hypothesis. The second model sees metal-ions transported from the Precambrian basement toward the orebody and precipitated. This formerly popular *magmatic-hydrothermal hypothesis* is no longer widely supported (Anderson and Macqueen, 1982).

Imprints of mineral-forming fluids are preserved in fluid inclusions in coarse sphalerite, carbonates, ~~fluorite~~ and barite. All MVT fluid inclusions are similar, showing the following characteristics (Roedder 1976, 1979): (1) the fluid density is commonly greater than 1.1 with salinities often greater than 15% by weight and up to 30%; (2) inclusions contain concentrated Na-Ca-Cl brines with minor amounts of K, Mg, Br and locally heavy metals such as Cu and Zn; (3) organic matter is common (not at Pine Point); (4) K/Na ratios are all higher than the highest values in oil field waters; (5) fluid temperatures on average appear to have ranged from 80°C and 200°C (Roedder, 1976, 1979). Item (4) can be interpreted that the ore-forming fluids are at least partly composed

of fluids from evaporite beds enriched in residual K. Fluid-inclusion data are commonly used as indicators to rule out ore-genesis models that feature cold surface waters alone as ore-forming fluids, including seawater or groundwater (Anderson and Macqueen, 1982). Newhouse (1932) considered  $\text{CaCl}_2$  contents as characteristic of waters transporting lead and zinc.

For the Pine Point ore bodies, fluid-inclusion studies by Roedder (1968a) suggested fluid temperatures between 50 and 100°C. They also "indicate the presence of other salts in addition to NaCl" (ibid., p. 444). Vasquez' (1968) results of semiquantitative analyses (Table 1.2) seem to confirm the presence of comparatively high amounts of  $\text{CaCl}_2$  in fluid inclusions in carbonates from Pine Point. In sample 0-42-48a3, the Ca-ion is even more abundant than the Na-ion. From freezing temperatures the salinity of fluid inclusions has been estimated to be about 23 percent in sphalerite (Roedder, 1968a) and considerably less in calcites (Roedder, 1968a, Vasquez, 1968).

Macqueen and Powell (1983) interpret the immature nature of the indigenous organic matter on the Pine Point property as indicating a generally low temperature environment (60°C maximum). Sulphur incorporated in MVT ores is generally isotopically heavy. Sulphate reduction by bacteria is said to be restricted to temperatures below 80°C.

Chloride-rich brines have the ability to leach trace quantities of metals from rocks (Ellis, 1968; Carpenter et al., 1974). Sedimentary source rocks could be shales, carbonates and also evaporite beds (Davidson, 1966), especially gypsum and anhydrite as shown by Thiede and Cameron (1978) for the Elk Point Basin south of Pine Point. In the Mississippi-Valley district, lead isotopes are of the radiogenic J-type variety, indicating a basin-brine history (Heyl et al., 1974). Lead isotopes at Pine Point, however, and in mining districts in England, Siberia, Tunisia and Italy are of the normal N-type variety, which implies a shallow crustal source according to Heyl et al. (1974).

Transport of metal-ions in NaCl brines would be hampered by the extremely low solubility of ZnS and PbS if significant amounts of H<sub>2</sub>S were present (Anderson, 1975).

For precipitation of ore, non-mixing models (one fluid carrying both metal and reduced sulphur) and mixing models (sulphur supplied at the site of precipitation) are applied. For the mixing model, two sources of reduced sulphur are available: sulphate in rock and sulphate in one of the participating fluids. Several MVT deposits are not in close proximity of an abundance of sulphate minerals (Anderson and Macqueen, 1982), but they may be engulfed in fluids containing dissolved sulphate.

In Pine Point, colloform minerals are abundant. They are rare however in the Mississippi-Valley district (A. Heyl, oral communication, 1982). Roedder (1968b) considers this form not as colloidal in origin but as the precipitation of minute druses of euhedral crystals from a fluid.

While the development of mineral sciences and related geological sciences lead to a succession of ore genesis models, modern hydrodynamic methods for analysis of groundwater flow have only been developed relatively recently. The advent of computers and refined analog models opened the way for the application of realistic models attempting to understand the basic rules of regional groundwater flow. Complex variations of topographic and hydrogeologic boundary conditions, and of geological parameters, were applied in the work of Tóth (1962, 1963), and Freeze and Witherspoon (1966, 1967), based on the fundamental work of Hubbert (1940, 1957).

More recently, an attempt has been made to couple selected theoretical conditions of both hydrodynamical and hydrochemical nature with a simple geologic history and framework in a numerical model of relative mathematical complexity. From the infinite number of possible quantitative answers, Garven (1982) and Garven and Freeze (1982) report a 90,000 year

accumulation for zinc showings of up to 3 ppm in the modelled carbonate aquifer system. The limitations of the modelling methods, the available computer storage space and processing time restricted the choice of parameters and boundary conditions to very simple model conditions only. Groundwater can be even more effective than this in the creation of ore bodies. Jonasson et al. (in press) report an orebody of 80,000 tons of 30% Zn-ore accumulated within 8,000 years; Cannon (1955) found a post-glacial accumulation of 2000 tons zinc and lead in peat beds in Orleans County, N.Y.

#### DEDOLOMITIZATION

Dedolomitization is the reverse process of dolomitization and is brought about by solutions with a high  $\text{Ca}^{2+}/\text{Mg}^{2+}$  ratio reacting with dolomite to form calcium carbonate (Evamy, 1967), according to the equation

The work of de Groot (1967) indicates that dedolomitization can only take place where the  $P_{\text{CO}_2}$  is much lower than 0.5 atm, temperatures are not higher than 50°C and a high rate of water flow is present. The former two conditions suggest that, in nature, dedolomitization is a near surface, process. Because of this the presence of de-dolomite may be used to infer that near-surface diagenesis has taken place (Evamy, 1967, p. 1205).

Yanat'eva (1955) studied the effect of dissolved gypsum on the solution of dolomite. She demonstrated that the presence of calcium sulphate in solution enhances the rate of the incongruent solution of dolomite at low  $P_{\text{CO}_2}$  (reported in Evamy, 1967, p. 1204).

Evamy (1967) showed that dedolomitization can lead to an enhancement of porosity and permeability as well as, at a later stage, cementation with  $\text{CaCO}_3$ .

Dedolomitization so far has not been identified as an important diagenetic process in the Pine Point area. It is conceivable, however, that this process caused precipitation of some of the secondary calcite present in the Pine Point dolomites.

Lippmann (1973, p. 166), however, is doubtful whether the process described by the above equation is of any consequence in nature. He feels that "the process interpreted as dedolomitization may consist actually of the preferential dissolution of calcian dolomites accompanied by the reprecipitation of calcium carbonate" (ibid., p. 166, 167).

#### SEQUENCE OF DIAGENETIC EVENTS

Within the Western Canada Sedimentary Basin, dolomitization and associated development of highly permeable systems occurred in areas of several hundred kilometres in length and width, from Pine Point in the east into the area of northeastern British Columbia (Skall, 1975: Presqu'ile; Morrow, 1975: Manetoe dolomite).

The Presqu'ile facies in the NWT is similar to the Manetoe dolomite in NE British Columbia (Morrow, 1975). Morrow (personal communication, 1982) identified four major diagenetic changes: (1) creation of solution porosity (solution collapse breccia) and subsequent dolomitization of host rocks with coeval infilling of porosity with white mega-crystalline dolomite, (2) precipitation of translucent crystalline quartz, coeval with or followed by the appearance of bitumen (high sulphur asphaltene), (3) growing of stylolithes cutting across the previous structures and (4) precipitation of sphalerite and galena.

Precipitation of the coarsely crystalline Presqu'ile-type dolomite was associated with the development of the karst-type dolomitic aquifers. The aquifer-like dolomite system were well developed before precipitation of the ore took place. Ore-forming solutions then flowed along available permeable systems and, under favourable circumstances, orebodies were formed. Presqu'ile dolomite may have been remobilized or dedolomitized and reprecipitated. This process would cause the often complicated

paragenesis of minerals found today at some of the Pine Point orebodies (Krebs, 1982, unpublished manuscript). The precipitation of ore may also have increased the porosity, because of the formation of hydrochloric acid according to the chemical reaction

## METHODOLOGY

### SOURCES OF DATA

Engineering data for dewatering boreholes and pump tests at open pits were provided by the engineering department of Pine Point Mines Ltd. (K. Durston, T. Healy).

A total of 497 isotope, 82 bacteriological and 620 hydrochemical samples were collected by NHRI (K. U. Weyer, W. C. Horwood-Brown). The chemical samples were analysed by commercial laboratories (Diamin Laboratories, Calgary, R. Barefoot; Chemex Labs (Alberta) Ltd., Calgary, D. Laberge; Seakam Oceanography Ltd., Sydney, B.C., D. Thomas; Chemistry Laboratories, University of Calgary, F. W. Bachelor) and by the Water Quality Laboratory of Environment Canada in Calgary (M. Korchinsky). Isotope data were determined by the Stable Isotope Laboratory of the University of Calgary (H. R. Krouse). Bacteriological water samples were cultivated and analysed by the Microbiological Laboratories of the Environmental Protection Service of Environment Canada in Edmonton (J. Bell).

Discharge measurements of major rivers were performed by the Fort Smith office of the Water Survey of Canada (WSC: A. Wilson, D. Dube, T. Wilson), discharge measurements at karst springs and at Pine Point dewatering channels were performed by NHRI (Weyer, Horwood-Brown, J. A. Banner). Gaging stations at karst springs were devised by NHRI (Weyer, Banner) and installed jointly by WSC (A. Wilson, D. Dube) and NHRI (Banner, Weyer). Automatic time-lapse cameras were built and installed at several spring sites by NHRI (Banner; Banner, Weyer; description of system in Banner and van Everdingen, 1979).

Cores of the oil wells CDR Wood Buffalo C-74, CDR Wood Buffalo L-42, and Iskut Little Buffalo K-22 were described with regard to porosity features by NHRI (Weyer) at the core storage facilities of the ISPG in Calgary. The core of the mineral exploration hole Pyramid 202A was examined at the open-air core-storage facilities of Pine Point Mines Ltd. in Pine Point, N.W.T., together with D. Adams of Cominco Ltd. D. Adams also determined the facies of 14 core samples from CDR Wood Buffalo C-74 used for permeameter testing. The ISPG made 8 core samples available for porosity and permeability measurements (NHRI: Banner, Weyer; Core Laboratories-Canada Ltd., Calgary), 8 core samples for x-ray diffraction analysis (ISPG: A. E. Foscolos, J. Wong, A. Heinrich), 2 core samples for petrological thinsection analysis (ISPG: H. Geldsetzer, O. McEwan), 1 core sample for analysis of organic components (ISPG: W. Kalkrenth, A. E. Foscolos, K. Pratt) and 1 core sample for infrared spectrometric analysis (ISPG: G. P. Michael). Samples of mineral precipitates in dewatering ditches at Pine Point were analysed by K. Werner, Geological Survey of NW, Krefeld, West Germany.

D. Sangster (GSC, Ottawa) searched the CANMINDEX and related computer files of the GSC for Pb and Zn-deposits occurring east of Pine Point in the Canadian Shield on NTS maps 75 E, F, J, K, L, O, P and 85 H, I.

#### METHODOLOGY AND DATA PROCESSING

At chemical sampling sites pH, Eh (calomel-electrode), temperature (ASTM) and conductivities were measured. Up to six individual water samples were taken at each sampling site for major ions, trace ions,  $H_2S$  in water,  $\delta^{34}S_{SO_4}$ ,  $\delta^{34}S_{HS^-}$  and  $\delta^2H$  determinations. Major-ion and  $\delta^{34}S_{SO_4}$  samples were filtered with Whatman 40 paper, the trace-ion samples with Millipore 0.45  $\mu m$  (bottles were acid washed). The  $HS^-$  samples and the  $\delta^2H$  samples were not filtered. The following additives were added in the field:

$\delta^{34}\text{S}$ in $\text{SO}_4^{2-}$	- conc. $\text{HCl}$ , $\text{BaCl}_2$
$\delta^{34}\text{S}$ in $\text{HS}^-$	- $\text{NaOH}$ pellets, $\text{Cd}$ -acetate
$\text{HS}^-$	- $\text{Zn}$ -acetate
trace ions	- $\text{HNO}_3$

Bottles used were Nalgene linear polyethylene, except for  $\delta^2\text{H}$  where glass bottles were used. All water samples were sent by air freight (non-freezing) to the laboratories as soon as possible and, in the commercial laboratories, analyses were started upon receipt of the samples.

Nearly all samples were analysed for  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Cl}^-$ ,  $\text{SO}_4^{2-}$  and  $\text{HCO}_3^-$  ( $\text{CO}_3^{2-}$ ), and for sulfur and hydrogen isotopes, most for  $\text{H}_2\text{S}$ , and some for trace ions and for oxygen isotopes in  $\text{SO}_4^{2-}$  and  $\text{H}_2\text{O}$ . Chemical analyses were done according to standard methods as described by Alberta Environment (1977) and Environment Canada (1979).

Cultivation and incubation of bacteriological samples were started at Pine Point in the moveable microbiology laboratory of EPS, Edmonton, by J. Bell, G. Elliot, and F. Zaal. The moveable laboratory was driven back to Edmonton and upon completion of incubation samples were counted with the MPN (Most Probable Number) - system.

Discharge measurements by the Water Survey of Canada (WSC) made use of the Price cup-current meter and of the time-saving standard North-American two-point method (velocity measurements at 0.2 and 0.8 of the total water depth; WSC, Field Manual) introduced by Cunningham (1883) and Teichmann (1883). Discharge was calculated in the field by means of arithmetic methods. The accuracy of the discharge determination is said to be between three and five percent. In shallow water depth (less than about one meter depth) the one-point method was used by WSC (0.6 of total water depth). The accuracy of this method is somewhat less than that of the two-point method.

NHRI measured discharge at karst springs, at small creeks and at the Pine Point dewatering channels, using the Ott-C1 screw type minicurrent meter with six exchangeable propellers with 2 to 4 cm diameter.

Investigation of return flows from dewatering ditches to the pumps called for extreme accuracy in NHRI's discharge measurements. The time-consuming standard European multi-point method (also called vertical velocity method: Corbett, et al. 1943, Buchanan and Somers, 1969) was applied. Discharge was calculated using Harlacher's method (Harlacher, 1872, 1881, United Nations, 1954; depth-velocity, integration method) and the computer program CURMET (Weyer, 1973) which calculates, documents and plots all field data and results. This program's calculation method closely follows graphical integration methods. All six propellers had been calibrated previously by the manufacturer and the actual calibration measurements had been supplied to us. These calibration data were analysed interactively with the program METCAL (Ruitenbeek and Weyer, 1979a). Instead of the standard two equations, an improved set of five revolution-velocity equations were then determined.

The multipoint measurement method and its documentation, calculation and plotting with the program CURMET allows an accurate and reproducible error determination. We were able to reduce the error for small flows to well under 1 percent. Appendix 1 shows an example of two consecutive discharge measurements about 1.2 km apart in the dewatering channel of the open pit S-65 at Pine Point Mines. The two measurements differ by only 0.4% (78.4 compared to 78.7 l/sec).

In the Pine Point area, three discharge gaging stations were operated by NHRI from 1978 to 1982 in areas only accessible by helicopter; two at karst springs close to and within Wood Buffalo National Park, the third one at a saltwater creek west of Buffalo River close to Great Slave Lake. The two gaging stations at the karst springs were equipped with bellows-type recorders for monitoring of back pressure in bubbling

lines. Attempts to determine a stage/discharge curve were hampered by differential movements of the solid surface in the area of the Angus Tower Spring, due to variations in groundwater discharge, and by a wide channel and low flows at the Halfway Spring.

Altimeter readings for the two karst springs Angus Tower Spring and Halfway Spring were taken on August 13, 1981, with a Wallace & Tiernan surveying altimeter model FIA-112-1-3 in comparison with a known altitude at Fort Smith Airport (initial control reading: 11:00; final control reading: 21:20). Between stations the instrument was transported by helicopter over a total distance of 190 km each way. Elevation readings at the springs were at 12:10 (Angus Tower Spring) and 12:55 (Halfway Spring).

In general mid-day readings and long transportation distances are of disadvantage for accurate readings with altimeters. Nevertheless, the difference between the readings at the two springs might be quite reliable as they were taken only 45 minutes apart. Altimeter readings, linearly corrected for barometric changes, were 796 ft/243 m for Angus Tower Spring (Helicopter 780 ft /238 m) and 754 ft /230 m for Halfway Spring (Helicopter 754 ft / 221 m.). Corresponding elevation differences would be 42 ft/12.80 m and 71 ft /21.60 m. In lieu of more accurate levelings we assume the elevation of Angus Tower Spring to be about 790 ft/ 241 m while Halfway Spring would be about 750 ft / 229 m. Hence the elevation of the overflow at Halfway Spring would be about 40 ft /12 m lower than that at Angus Tower Spring.

For independent recording of water levels, time-lapse cameras were installed at two of the three gaging stations. An additional camera was installed for one year at a prominent but dry sulphur spring near the east bank of the Buffalo River close to the formerly artesian Pine Point borehole 104.

The large number of discharge, chemical, borehole and geologic data accumulated necessitated the use of computer data banks for storage and retrieval. For this purpose four major computer data storage and retrieval systems were developed: DISBNK, CHEMBNK, BORBNK and GEOBNK. DISBNK stores about 10 000 digital readings (6 hour interval) of the discharge at the

Buffalo River gaging station of WSC; CHEMBNK stores the results of chemical field measurements, laboratory analyses and elevation and position data, together about 35 000 pieces of information; BORBNK contains about 20 000 data for 1,507 mineral exploration boreholes and 64 oilwells in the study area. GEOBNK contains more than 50 000 data of hydrogeologic, karstic, mineralogical and organo-chemical (bitumen, tar, oil) nature.

Data from the data banks are processed by means of the following computer programs:

- DISBNK:

METCAL (Ruitenbeek and Weyer, 1979a)

HGRAPH (Ruitenbeek and Weyer, 1979b)

- CHEMBNK

SEMILOG (Horwood-Brown and Weyer, 1980)

ISODATA (Horwood-Brown, Krouse and Weyer, 1977)

CHEMBNK (Horwood-Brown, 1979)

- BORBNK:

NEARLC (Horwood-Brown and Weyer, 1982)

GSRUG (Geodetic Survey of Canada, 1973)

- GEOBNK:

SRHGEO (Horwood-Brown, 1982)

The program CHMEDT and SRHGEO have been used as interface for commercially available contouring and 3-D plotting programs, i.e. SURFACE, TERRAPLOT, etc.

## REPRESENTATIVENESS OF BOREHOLE DATA

The geologic and hydrogeologic evaluation of borehole data was based on logs of about 1,500 mineral exploration boreholes from files of the Mining Division offices of DIAND in Yellowknife (W. Padgham) and Ottawa (D. D. Brown). It also made use of logs of 64 oil wells stored at the Institute of Sedimentary and Petroleum Geology (ISPG: W. J. Banning) of the Geologic Survey of Canada (GSC), and at the Alberta Energy Conservation Board, both of Calgary (see Appendix 2 for list of boreholes; see table 1.3 for hydrogeologic evaluation of oil wells). Altogether more than 230 km of boreholes have been evaluated; the depth of the boreholes ranged from 9 meters to 1518 meters with an average depth of 147 m. The majority of these holes had been cored in the bedrock (D in column T of Appendix 2).

Upon request, Westmin Resources, Vancouver (A. Soregaroli), freely made available the locations and elevations of their exploration boreholes in the Pine Point area. Westley Mines of Vancouver, through the Geology Department of DIAND, Yellowknife, also made available the locations of 7 of their exploration boreholes in the area. A limited number of borehole locations and elevations were finally made available from Pine Point Mines (T. Healy, K. Carter). Some of their data needed to be corrected, some may still need to be. Approximate positions of many boreholes were determined using claim maps made available by the office of the Mining Recorder of DIAND in Yellowknife, and by using a 1974 property map of Pine Point obtained from government files.

Stratigraphic data were taken from borehole logs as far as listed and acceptable. For about 50 percent of the boreholes, the stratigraphy had to be determined by NHRI (Weyer) from the lithological description, the fossil contents and a comparison with listings of boreholes nearby. A suitable stratigraphic system was devised by NHRI (Weyer) in discussions with D. Adams of Cominco Ltd., Calgary, modifying Skall's (1975) system. Extraction of geologic and hydrogeologic data was done by NHRI (Weyer, Horwood-Brown, R. Gardner). Regarding geology, there was no significant input received from the Geology Department of Pine Point Mines Ltd. (N. Zarkos, J. Collins, R. Armstrong, K. Carter).

Borehole logs for about 1500 boreholes in the study area were obtained from the Mining Recorder offices in Yellowknife and Ottawa. Two questions arose:

- (1) how representative are the submitted borehole logs, and
- (2) how accurate are the interpretations adopted by us?

In answer to question(1) we will consider stratigraphic information and other geologic information separately, followed by discussion of information on borehole position and elevation. Unfortunately, many of the borehole logs submitted to the Mining Recorder do not contain stratigraphic information (Appendix 2, Column LS, L - contains lithologic information, S - contains stratigraphic information) which includes many submitted by Pine Point Mines in the past. All borehole logs from Westmin Resources, as well as most of the more recent submissions by Pine Point Mines, however, contained detailed stratigraphic data. Because of changing stratigraphic concepts, some of the older pre-1970 submissions by companies needed to be revised. The stratigraphy of all relevant boreholes was determined and re-evaluated by us. We accomplished this cumbersome and time-consuming task using a computer program for locating and displaying distances and directions to neighboring boreholes (Program NEARLC, Horwood-Brown and Weyer, 1982). Stratigraphic markers (Amco-Shale and E-shale) and 'iterative' comparison with established stratigraphy in nearby holes aided in the evaluation. With increasing experience and knowledge of some of the finer points of local stratigraphy and facies, the stratigraphic evaluation became more reliable. Naturally some of the early holes had to be redone. Partway through this process, D. Adams of Cominco Ltd. provided valuable assistance by cross-checking our evaluations with his own interpretation, and suggesting final adjustments of our evaluation procedure. We now consider our stratigraphic evaluation to be quite reliable. Computer listings of the geological evaluation have been sent to Pine Point Mines and were found acceptable by their geology department (K. Carter, personal communication, 1982).

In regard to geologic and hydrogeologic information the situation is a little more complex. From a comparison of borehole logs submitted more than once it became obvious that all the information collected is not always included in the records submitted to the Mining Recorder. Also, some geologist have certain preferences stressed above all other points, like fossil associations, facies considerations, classification of breccia types, cavity fillings, core losses and recovery rates, classification of porous systems such as vugs, fractures, pin point and intergranular porosity, and listing of minerals and organic material. Hydrogeologic parameters such as water flow from the hole and its origin at a certain depth, were in general poorly described. Understandably, this information was only provided in a minority of cases, because it may have been regarded as unnecessary information in view of current ore genesis and exploration concepts.

It is clear that all of the above reasons have a tendency to lead to an under-representation of any one particular rock property in the Pine Point area. This tendency would be even more serious for deeper strata because the number of boreholes penetrating these strata is smaller.

A further cause for under-representation originates in our own learning process during transcription of the data into computer files. In the first attempt to collect sufficient geologic data we limited ourselves to about 400 boreholes chosen at random and evaluated for a few characteristics, like vugs and cavities, only. It soon became clear, however, that all available borehole logs would have to be evaluated. In the course of this evaluation, the number of parameters recorded kept growing to about one hundred, apace with our insight into the geologic and hydrogeologic intricacies. Also, we would identify a feature more readily as our understanding of the geology grew. Unfortunately, we did not get the opportunity to include earlier omissions in a second round of data transfer. Editing had to be curtailed to the bare minimum because of managerial directives. Nevertheless, we feel that we have eliminated the major discrepancies.

Our biggest problem and most time consuming task was the determination of the precise location of the boreholes, and their surface elevations. Again, many submissions to the Mining Recorder were found woefully inadequate. Upon inquiry, Westmin Resources made the precise coordinates and elevations of all their boreholes readily available. Pine Point Mines did make similar data available only for a limited number of holes towards the end of our data-gathering period. Fortunately we were able to locate, at the mining geologist's office in Yellowknife, a Pine Point property map that showed the position of a number of holes. Positions of other boreholes of Pine Point Mines and of other exploration companies were determined from claim maps, which is a very time-consuming process. The claim maps were provided by the Mining Recorder's office in Yellowknife. D. Adams of Cominco Ltd. made available coordinates for about 50 'exotic' boreholes, the position of which he had determined previously. For the Pine Point property we checked the position of boreholes against the site descriptions given in the bore logs (as for example cut lines etc.), and found that in extreme cases coordinates submitted to the Mining Recorder's office were off by more than 30 km. We believe that by now our location data are accurate to within 50 feet (15 m) in most cases; in some extreme cases they may be out by up to 500 m.

Location data were recorded using four systems: geographic north, UTM (zones 11 and 12), Pine Point engineering coordinates, and Pine Point geology coordinates. All data were then transformed into the rectangular UTM system with an extended zone 11, using the program GSRUG made available to us by the Geodetic Survey of Canada (P. Henderson).

For the Pine Point property, data on elevation were taken from borehole listings. Some additional data were later received from Pine Point Mines. The data were first checked against neighbouring boreholes and eliminated if obviously erroneous. Then elevation data were contoured with the commercially available contouring program TERRAPLOT,

using a scale of 1:250,000. The position of isohypses then was compared with those on 1:250 000 topographical maps. Good agreement was found except for some localized 'holes' and 'mountains'.

Eliminations or, in some obvious cases, appropriate corrections were made. We are now confident that elevation data used for the plotting of the top of Amco shale, E-shale and bedrock are adequate.

In summary it can be said that the regional computer plots of specific geologic or hydrogeologic properties of the rocks in the Pine Point are, to the best of our knowledge, reliable with regard to position and elevation, within the limitations described above. They rather under-than over-represent the properties shown.

## 2. PRINCIPLES OF REGIONAL GROUNDWATER FLOW

### BACKGROUND

The concept of regional groundwater flow may not be familiar to all mining and ore geologists. It is therefore discussed in some detail here. First of all, the definition of the term groundwater needs some clarification. Groundwater is not only the rather thin veneer of freshwater in the overburden, as is sometimes assumed, but any aqueous solution in the subsurface in (hydrodynamically) saturated state, whether it be fresh, saline or salty. Natural brines in the subsurface are considered part of the groundwater system. The concept of density stratification in groundwater is a myth in as far as it assumes that denser fluids automatically concentrate downdip in the deeper parts of basins. All fluids, both aqueous ones of different density and hydrocarbons, are moved by the same coupled forcefield integrating mechanical, chemical, osmotic and temperature related forces (Weyer, 1978a).

The door leading to the modern development of the science of regional groundwater flow was opened by Hubbert (1940). His fundamental message about gravitational groundwater flow was visualized in one simple figure, here reproduced as Figure 2-1.

-----  
Figure 2-1  
-----

Before Hubbert's publication and for decades after he published his paper, thinking on groundwater flow was dominated by the Dupuit-Forchheimer assumptions (Dupuit, 1863, Forchheimer, 1930) whereby the flow was assumed to be horizontal and the hydraulic gradient assumed to be equal to the slope of the groundwater table. Hubbert's (1940) figure showed the water to flow downwards under the recharge area of the highland (flow directed through the groundwater table into the groundwater body if recharge occurs) and upwards under

the discharge area of the lowlands (flow directed upwards from the groundwater body into surface water or towards evaporation). It is difficult to think of any other single figure which has exerted more influence on the development of modern thinking about regional and basin-wide groundwater flow than Hubbert's (1940) ingeniously simple visualization of complicated physical and mathematical derivations.

If we were to insert open ended standpipes (piezometers) into the groundwater body along a flow line from the recharge to the discharge area than the water columns in those pipes would rise according to the energy level encountered at the open bottom end of the pipes.

Figure 2-2  
-----

Figure 2-2 shows the top of the water columns in the piezometers in the recharge areas (numbers ② and ③) to be lower than the groundwater table; in the discharge area the water column in piezometer ④ rises higher than the groundwater table. If the groundwater table is close to the surface of the valley and if the head in the piezometer is high enough, then the flowing conditions of an artesian well will occur. Figure 2-2 shows that flowing conditions can occur even if an artesian aquifer or an aquitard are not present. The physical nature of the forces involved were discussed in detail by Weyer (1978a). In the following we will focus our attention on artesian conditions in geological systems with aquifers (highly permeable layers) and aquitards (layers with lower permeability).

In this report the term artesian is used in its original meaning as flowing well. The term originates from the area of Artois in France where famous flowing wells were drilled during the middle ages. Jacob (1939, 1940, 1950) changed the meaning for North American engineering by using it for "confined water". In Jacobs usage, artesian stands for water in a confined aquifer, with a head higher than the top

## 2.3

of the aquifer. This report uses the term artesian in its original meaning in the same way as the french "artésien" and the german "artesisch".

-----  
Figure 2-3  
-----

Figure 2-3 introduces an aquifer (relative permeability  $K = 100$ ) of limited extent located below a less permeable aquitard (relative permeability  $K = 1$ ). Flow is concentrated into the aquifer and directed towards the lowland. Vertical upward flow occurs in the lower lying part of the discharge area.

-----  
Figure 2-4  
-----

Figure 2-4 shows the general case of an artesian aquifer without outcrop. Flow is from the highland through the aquitard into the aquifer. Flow directions within the aquifer are from the highlands towards the valleys and then from the aquifer through the aquitard up into the valleys. The valleys have artesian discharge. The topography of the surface is reflected in the head distribution within the aquifer.

-----  
Figure 2-5  
-----

Proceeding one step further, Figure 2-3 is modified by extending the aquifer below the lowlands towards and underneath a lake as shown in Figure 2-5. The permeability contrast has been strengthened. Recharge is now in the highland and in parts of the lowland. An area adjacent to the lake and the lake itself have the potential for artesian wells. Again, recharge and discharge pass through the aquitard system while the regional flow is concentrated within the confined aquifer system.

We will show later that the schematic cross-section in Figure 2-5 depicts in principle the situation along a south-north cross-section from the Caribou Mountains to Great Slave Lake.

Artesian system thus do not need the artesian aquifer outcropping in an elevated mountain area, as is often postulated by conventional models (see Fig. 2-6).

#### HYDRAULIC TIME LAG

##### IMPORTANCE OF POSTULATE

Recently Tóth (1978, 1980) postulated hydraulic-time lags in the order of millions of years in the response of deep aquifers to changes in topographic boundary conditions. For the Red Earth region in Alberta he concluded that it would take 4 million years for the deeper aquifer to adjust completely to the instantaneous formation of a major river valley by erosion. As a computer program was used to calculate this time lag, the result of several million years carries the appearance of accuracy. Details of the program and the assumptions used are discussed in Tóth (1978, 1980).

If Tóth's results were universally valid, this concept would be of utmost importance for regional groundwater flow. Therefore, it deserves close scrutiny of all the assumptions involved and also a sensitivity analysis to assess the extent to which the assumptions determine the results of the computer calculations. The following discussion closely follows Weyer (1980).

##### FIELD RESULTS AND THEIR INTERPRETATION

Pursuing our topic, let us first list some of Tóth's (1980) field results and their interpretation (compare figure 2-7):

# Interdependence of permeability and hydraulic gradient.

Physically the interdependence of permeability and hydraulic gradient are expressed in Darcy's equation as formulated by H.Darcy (1856)

$$\vec{q} = -K \text{ grad } \phi \quad (1)$$

where  
 $\vec{q}$  = flux vector  
 $K$  = permeability  
 $\phi$  = potential.

Mathematically similar is the often used equation

$$q = -k \cdot \text{grad } h \quad (2)$$

where  
 $q$  = flux [ $L^3 L^{-2} T^{-1}$ ]  
 $k$  = hydraulic conductivity [ $L T^{-1}$ ]  
 $h$  = head [ $L$ ]  
 $L$  = length  
 $T$  = time

the head can be directly measured in the field piezometers installed in the field as shown in figure 2-2

more Detailed discussions of the physical meaning of the above properties are contained in Weyer (1978a). For the purpose of this paper we will consider the groundwater flux  $q$  to be constant

$$q = \text{constant} \quad (37)$$

the following mathematical and physical interdependence exists now between the permeability (hydraulic conductivity) and the hydraulic gradient (head gradient) in equations (1) and (2):

(1) — is

— is the head gradient along a flow path increased in a flow field, say by a factor of 10, then the permeability in the area of the increase of the gradient  $\frac{\partial h}{\partial l}$  (see fig 2-8a) is smaller by an equivalent amount (divided by 10)

— <sup>decreased</sup> is the head gradient along the flow path in a flow field, say by a factor of 10, then the permeability in the area of the decrease of the gradient (see fig 2-8b) is larger by an equivalent

amount (multiplication with 10).

// The above interdependence allows a reliable and direct determination of relative permeabilities from piezometric maps if ~~flow conditions~~ the condition in equation (3) holds true. This paper will make use of these interdependences to determine the relative permeabilities of least systems within and outside the Pine Point barrier reef system (see chapter 4).

---

Figure 2-7

---

- (a) In the Red Earth region a general similarity exists between the potentiometric surface in the deep and confined  $D_I$  unit and the present land surface. As pointed out by Tóth (1980, p. 141) this suggests "a genetic relation between the energy distribution in the basal or Devonian I ( $D_I$ ) conducting unit and the topographic relief."
- (b) According to Tóth (1980, p. 143) "the general flatness and low value of the potentiometric surface of the intervening Devonian III unit (Fig. 24 of Tóth 1980, p. 143) indicates that no energy from above is being transferred across that zone to the  $D_{II}$  unit". Therefore "the rather well defined correlation between the  $D_I$  unit (Fig. 23) and the land surface (Fig. 22) becomes an enigma" (Tóth 1980, p. 142-143; figure numbers refer to Tóth, 1980).
- (c) For the Red Earth region "the potential distribution observed today is not a result of the present topography despite the apparent correlation. Rather, it reflects the Pliocene topography which was similar to the present land surface" (Tóth 1980, p. 148). "As pointed out earlier, the time required for these potential differences to dissipate completely through the overlying rocks is approximately four million years. However, only about 100,000 years have elapsed since the previous boundaries changed; this was enough for the systems in groups  $D_{III}$  and higher to adjust but not for the ones below  $D_B$  - which explains the apparent relation between land surface and potentiometric surface in  $D_I$  *in spite of the intervening low energy drain in  $D_{III}$* ." (Tóth, 1980, p. 148, italics inserted).

## STATEMENT OF PROBLEM

In short the problem to be discussed is the following

- (a) the piezometric surface in the deepest layer  $D_I$  follows today's topographic surface suggesting hydraulically effective connections between the two and also quasi steady-state conditions in the system;
- (b) between the topographic surface and deep aquifer  $D_I$  there is a layer  $D_{III}$  with *mechanical* energy potentials that are lower than those in the deeper layer  $D_I$ , seemingly interrupting the hydraulic continuity between the topographic surface and the deep aquifer  $D_I$ ;
- (c) the author explains this situation by postulating non-steady state conditions with a time lag of  $10^5$  to  $4 \times 10^6$  years for the deep aquifer  $D_I$  to respond to the changed boundary condition of today's topography; consequently, the potentials in the deep layer  $D_I$  are said to reflect the Pliocene pre-glacial topography.

There are other explanations worth considering, for example, the possible existence of osmotic and chemical potentials not considered in Tóth's analysis. If such potentials occur then a discontinuity in the *mechanical* potential would appear within an existing hydrodynamic continuity; the thermodynamic principle of conservation of energy, in a situation like this, requires continuity only of the total potential but not of the mechanical one.

For this reason the model calculation of the time lag becomes of decisive importance. If the assumptions used and the calculation procedure itself are valid then the time-lag model would be convincing. If, however, the assumptions and the calculation procedure are not valid then Tóth's time-lag model would be only one of the possible explanations and its merits would have to be compared to other possible explanations.

## METHOD OF COMPUTER CALCULATION

According to Tóth (1978, p. 840) "the computation was based on the one dimensional non-steady-state solution of the heat flow equation for a multilayer column (Carslaw and Jaeger, 1959, p. 326) with hydraulic parameters substituted for equivalent heat flow parameters". From this statement it is clear that the computation procedure should be adequate for the problem considered, although one might also include variability of permeability as a function of potential gradients (forces).

PERMEABILITY OF CONFINING SEQUENCE  $D_A + D_{II} + D_B$ 

Regarding the parameters used, "values for K [hydraulic conductivity] and z [thickness of layers] were established from core analyses and drill stem tests and from stratigraphic information, respectively (Table 3), *as well as from the literature*. Storage coefficients were based exclusively on data from literature (Bredehoeft and Hanshaw, 1968)" (Tóth, 1978, p. 840, *italics inserted*). In Tóth's Table 3, K-values are  $2.5 \times 10^{-5}$  cm/s for Devonian I ( $D_I$ ) and  $8 \times 10^{-7}$  cm/s for the Devonian II. The table does not give any permeability value for the total of the confining layer  $D_A + D_{II} + D_B$ . Nowhere in the paper is it explained why these confining layers were assigned a permeability of  $5 \times 10^{-11}$  cm/s (Tóth, 1978, p. 841, Fig. 41). The low magnitude of  $5 \times 10^{-11}$  cm/s is somewhat surprising in light of the field value of  $8 \times 10^{-7}$  cm/s assigned in Tóth's Table 3 to one of these layers, the  $D_{II}$ . The average hydraulic conductivity of  $8 \times 10^{-7}$  cm/s was determined from drill stem tests. It is about 4 orders of magnitude higher than the value taken for the model calculations ( $5 \times 10^{-11}$  cm/s).

Because of the absence of literature references regarding the permeability value of  $5 \times 10^{-11}$  cm/s it is only possible to infer the source of the extremely low permeability value. Bredehoeft and Hanshaw (1968) was checked because reference had been made to this paper in regard to the storage coefficients taken. Their Table 2 (*ibid.*, p. 1100) lists selected hydraulic conductivities measured on specimens in the laboratory. It seems likely

that Toth's low permeability value may have originated from this table which reports laboratory test results for shale of  $6.0 \times 10^{-10}$  cm/s (Shale D, Neves Field, Montana), of  $2.0 \times 10^{-12}$  cm/s (Shale G, Williams Field, NW Mexico) and of  $1.3 \times 10^{-11}$  cm/s (Natural Shale).

All these test results were determined using unbroken laboratory specimens. They did not contain the fractures and fault zones that are present in the field. Therefore caution has to be applied in substituting laboratory tests for in-situ field data. Bredehoeft and Hanshaw (1968, p. 1100) expressed their opinion in the following way: "The few attempts at in-situ measurements of clay permeabilities that have been made suggest that the in-place permeability may be somewhat higher than that measured in the laboratory." Rowe (1972) obtained in-place permeabilities  $10^2$  to  $10^3$  times larger than those obtained from laboratory consolidation tests, due to the presence of fractures. Grisak and Cherry (1975) found the bulk vertical conductivity estimated for a site with fractured till one to two orders of magnitude larger than intergranular values estimated from laboratory tests on samples from the site.

In general there is a strong suspicion that effective field permeabilities can be 2 to 4 orders of magnitude higher than permeabilities from laboratory tests, because of fractures. Unfortunately, actual field tests are very rare. The ratio between field and laboratory permeabilities can be increased by an additional one or two orders of magnitude if regions are considered where fault zones, stratigraphic windows or reef pinnacles protrude through the confining layers. All these phenomena have been described for the confining layers in certain areas of the Red Earth region (Tóth, 1978, p. 810-811).

In view of the above, it does not seem justified to assume an effective hydraulic conductivity of only  $5 \times 10^{-11}$  cm/s for the confining layers. The reported value obtained by in-situ testing ( $8 \times 10^{-7}$  cm/s) seems to be more appropriate.

## SENSITIVITY ANALYSIS

Regarding a sensitivity analysis for the permeability parameter, Bredehoeft and Hanshaw (1968, p. 1099) used exactly the same mathematical system for their analysis of time-lags as did Tóth.

In their opinion, "in most circumstances anomalous pressure can only persist in a geologic sequence where rocks of low permeability predominate. For example, beds in the Gulf Coast deposits, which have unusually high pressures, are, generally, discontinuous sand bodies interbedded in a sequence where shale predominates. It is apparent that in a reasonably homogeneous, laterally extensive hydrologic unit of low permeability the flow will be almost entirely in a vertical direction. This greatly simplifies the analysis; the problem is that of one-dimensional non steady flow" (Bredehoeft and Hanshaw, 1968, p. 1099).

It appears unlikely that the extensive, fractured and faulted permeable layers of the Red Earth region meet all of the above requirements. In the Red Earth region a two-dimensional analysis might be superior to the one-dimensional calculation.

A sensitivity analysis for the permeability parameter was undertaken by Bredehoeft and Hanshaw (1968). Comparison of the two graphs of their Figure 3 reveals that the time lag calculated is directly related to the permeability used as input, in the following manner: a change in the permeability by an order of magnitude changes the calculated time-lag by an order of magnitude as well.

Using Tóth's assigned value of  $5 \times 10^{-11}$  cm/s, the resulting time-lag interval would be  $10^5$  to  $4 \times 10^6$  years. Using more likely permeability values (in the range of the field test,  $8 \times 10^{-7}$  cm/s) decreases the time-lag for a complete response of the confined deep aquifer by four orders of magnitude, from 4 million years down to only about four hundred years.

## VALIDITY OF LAG POSTULATE

It seems that the reflection of the topographical surface in the piezometric surface of the deep layer  $D_I$  in the Red Earth region might well be the expression of a genetic relationship and a quasi steady-state regional groundwater-flow system, caused by today's topography, not by Pliocene conditions. Because of the uncertainty in the permeability values, the mathematical model does not support the transient concept presented by Tóth (1978, 1980).

The hydraulic time-lag concept has therefore not been considered in the present analysis of regional groundwater flow in the area south of Great Slave Lake.

### 3. FRAMEWORK FOR GROUNDWATER FLOW IN STUDY AREA

#### TOPOGRAPHY

The groundwater table constitutes the most important boundary condition for a gravitational groundwater flow system. Groundwater tables in turn closely follow the topographical surface of the earth. It is therefore that the topography of a region determines the distribution of recharge and discharge areas. The overall direction of flow is always from the highlands towards the lowlands.

The area dealt with in this report extends over about 250 km from the Caribou Mountains in the south (Fig. 3-1, elevation up to 1000 m) to Great Slave Lake in the north (elevation 156 m). In the east-west direction the area extends for about 200 km from west of the Hay River (elevation 250 m to 156 m) to the Slave River in the east (elevation 200 m to 156 m).

-----  
FIGURE 3-1  
-----

The topographic framework would indicate groundwater flow from the recharge area in the Caribou Mountains in a radial pattern to all sides. Exactly that pattern has been found by Hitchon (1969a, see Figure 1-1 of this report).

Additional recharge would occur in the low-lying foreland between the Caribou Mountains and the artesian discharge areas, similar to the situation shown in the schematic cross section in Figure 2-5.

#### GEOLOGY

##### SUBSURFACE INFORMATION

Parts of the geologic description of the area are based on the evaluation of 1507 mineral exploration boreholes and 64 oil wells in the area (Appendix 2). The distribution of the mineral exploration and oil boreholes adjacent to Great Slave Lake is shown in Figure 3-2A;

*add the climatological data*

## CLIMATOLOGICAL DATA.

### GENERAL INFORMATION

In the area between Great Slave Lake and the Peace River climatological data have been recorded at eight stations, all of them with broken records (compare table 3.1). The most complete records exist for Fort Smith Airport (east of Caribou Mountains), and for Hay River Airport (south shore of Great Slave Lake), less complete ones are available for the Fort Resolution Airport (south shore of Great Slave Lake), for Hay River Paradise Gardens (about 30 km south of Hay River Airport) and for the High Level Airport (SW of Caribou Mountains). Very incomplete records exist for Angus Tower and Pine Point (both not too far away from the south shore of Great Slave Lake). No climatological data were available for the Caribou Mountains plateau.

In general total precipitation (1961-1980 normal) between Great Slave Lake and Caribou Mountains is between 305 and 360 mm/a, with 32 to 47% deposited as snow during the winter (Table 3.2). Annual mean daily temperatures range from -4.0 to -3.3°C with extremes from -53.9 to +35.6°C. Records from Pine Point (1975-1980 normal only) appear to be an<sup>a</sup>omal with a total precipitation of only 244.9 mm and a relatively warm annual mean daily temperature of -2.4°C. This has probably been caused by anomalously low precipitation and warm temperatures during the time interval from 1975 to 1980.

Climate in the High Level area (SW of Caribou Mountains) appears to be wetter and warmer than that in the flat lands towards the north and east of the Caribou Mountains.

Based on methods by Morton (1983) aerial values of evaporation and sublimation have been calculated (Morton 1983, personal communication for three climatological stations in the area (table 3.2-6). At all three stations sublimation of moisture from the air prevails during winter months (November - March) while evaporation prevails during the rest of the year (April - October). According to Morton (1983, personal communication) "actual evaporation" is about equivalent to precipitation at Ft. Resolution and 20 to 30% less at Ft. Smith and Hay River. It appears that these comparatively high evaporation values can only be reached if water would be available for evaporation during the whole length of the evaporation season. Hence, for the purpose of this report, the above evaporation values should be considered potential evaporation. They should not be taken to determine possible ranges by comparing precip to the groundwater system by comparing precipitation with evaporation.

Climate in the Caribou Mountains plateau should be colder and possibly wetter due to higher topographic elevations of up to 1000 m.

#### OCCURRENCE OF DRY YEARS

Available monthly, annual and normal precipitation and temperature records and indices for the calendar years 1975 to 1982 of the climatological stations, Fort Smith Airport, Hay River Airport, High Level Airport, Fort Resolution Airport, Hay River Paradise Gardens and Pine Point (Station B in table 3.1) are contained in tables 3.3 A to F. For the station Angus Tower records do not exist for this time interval. Complete records for this time interval exist only for the stations Fort Smith, Hay River Airport and High Level Airport. Of these three stations only Fort Smith and Hay River Airport have reliable 1951-1980 normal (code 1, table 3.2) while High Level Airport 1951-1980 normal is somewhat less reliable (code 8, table 3.2).

Records for the stations Fort Resolution Airport, Hay River Paradise Gardens and Pine Point between 1975 and 1982 contain a significant number of data gaps leading to a lack of annual values for precipitation and temperature.

Because of the above reasons the following discussions of the climate between 1975 and 1982 are based mainly on records for the three main stations Fort Smith Airport, Hay River Airport and High Level Airport. Of these three stations Hay River Airport

is best representative for the study area between Great Slave Lake and Caribou Mountains, due to its geographical position towards the north of the Caribou Mountains.

Table 3.4 presents a synopsis of the annual snowfall (in water equivalents) rain and total precipitation for these three stations by (A) calendar year and (B) water year (October 1 to September 30). Table 3.5 (A to C) lists the monthly and seasonal snowfall and water equivalent of the snowfall for the winters 1975 to 1982 in comparison to the 1951 to 1980 normals, while table 3.6 A and B show the snow depth at the end of the month.

Tables 3.7, 3.8 and 3.9 have been extracted from the previous tables 3.1 to 3.6. They list by calendar year (A) and water year (B) for the three main climatological stations rain, snow, snow water equivalent and total precipitation in percentage of 1951 - 1980 normal (table 3.7), as % deviation from the 1951-1980 normal (table 3.8) and finally as a synoptic symbolic classification table (table 3.9)

24 22 d

and type 3-1a)  
Table 3-7 shows in turn shows the 1945-1983 records change of precipitation, rainfall snow fall (depth and water equivalent) and total precipitation for the ~~about~~ station Bay River ~~Drift~~. This station is ~~closest to our investigation~~ within the area of investigation and about 80 km distant from Pine Point. It appears that

From the table 3-7 to 3-10 it appears that in general those prevailed since about 1969 a trend to dry years. The trend important for the groundwater recharge is the water equivalent snow fall. Corrected calculations for the water year (29 October - September) are contained in the table 3-7 to 3-9. They show that the winter 1975/76 was a normal year, while a above normal year, while the winters period 1976/77 to 1980/81 were dry to very dry and the season 1981/82 was about normal again.

In Table 5 the occurrence of the dry years ~~has~~ is ~~considered in~~ will be compared with the pumping record in order to assess ~~the~~ the relative effects on ground water flow.

In the following we will the effect of the dry years on the lake levels in Great Slave lake and on the discharge of three main rivers in the area will be discussed. Table 3-1/2 lists the lake level fluctuations from ~~from~~ ~~for~~ of Great Slave lake ~~for the period~~ at the stations Yellowknife and Fort Resolution for the ~~stations~~ period 1970 - 1982.

During this period ~~the~~ the fluctuation of the <sup>annual</sup> minimum lake level is about 1.5 ft (50 cm) at Yellowknife and about 2.5 ft <sup>(75 cm)</sup> at Fort Resolution. The small magnitude of these fluctuations exclude a significant effect ~~on~~ on the regional

- 2 - 4

flow systems in the area for the area under investigation.

The dry years showed a more pronounced effect on the discharge in the rivers (listed from west to east) Hay River, Buffalo River and Little Buffalo River as measured at gaging stations operated by the Water Survey of Canada. The 1975-1982 monthly summary of daily discharge at these stations are contained in tables 3-13

For the period  
1975-1982

A, B and C. The Annual discharges are related to the total precipitations 1975-1 in tables 3-13 A, B, C, and

Tables 3-13 A, B and C show that in terms of mean flow annual flow the years 1980 to 1982 appear as extremely dry years for the Buffalo and Hay River (with 1980 probably the worst year). At the Little Buffalo River the years 1978 and 1980 to 1982 appear as dry years (record for 1981 is sufficient).

1977

In chapter 3 & 5 ~~are~~ these records will be compared to discharge records of springs in host springs in the area and to the pumping record at Pine Point mines. It will be shown ~~the~~ how the changes in the discharge records at the host springs time-wise correlate with the pumping pattern at Pine Point mine but not with the discharge records of ~~some~~ the rivers in the area.

# HAY RIVER

WSC - Station No. 070B001

	Total discharge [10 <sup>9</sup> m <sup>3</sup> ]	mean flow [m <sup>3</sup> /s]	unit area, discharge [L/s . km <sup>2</sup> ]	equiv. precipitation 2) [mm]	total annual precipitation 3) [mm]	% of annual precipitation
1975	3.15	99.6	2.08	65.6	339.4	19
1976	6.02	190.	3.97	125.2	323.9	39
1977	7.25	230	4.80	151.4	234.4	65
1978	3.51	111	2.32	73.2	274.8	27
1979	5.24	166	3.47	109.4	230.4	47
1980	0.623	19.9	0.42	13.1	287.0	5
1981	1.62	51.5	1.08	33.9	311.1	11
1982	1.87	59.3	1.24	39.0	260.7	15
mean 1964-1979	3.53	112	2.34	73.7	306.1	24
1) size of catchment area above gaging station: 47,900 km <sup>2</sup> . 2) 1 L/s. km <sup>2</sup> is equivalent to 31.536 mm precipitation per annum 3) at Hay River Airport.						

TABLE 2B 3-13 B

Little Buffalo River  
MSC Station No. 07PB002

	total discharge [10 <sup>9</sup> m <sup>3</sup> ]	mean flow May-Oct. [m <sup>3</sup> s <sup>-1</sup> ]	mean flow annually corrected	unit area 1) discharge [ℓ s <sup>-1</sup> km <sup>-2</sup> ]	equivalent precipitation 2) [mm]	total annual precipitation 3) [mm]	% of annual precipitation
1975	0.111	6.98	4.23	1.18	37.2	455.8	8.2
1976	0.101	6.38	3.19	0.886	27.9	310.4	9.0
1977	0.053	3.38	1.69	0.469	14.8	363.9	4.1
1978	0.026	1.67	0.98	0.272	8.6	279.0	3.1
1979	0.070	4.43	2.22	0.617	19.5	255.7	7.6
1980	0.0120	0.380	0.190	0.0528	1.7	304.8	0.6
1981	insufficient record						
1982	0.0427	1.35	0.68	0.189	6.0	347.6	2.1
mean 1967-1979	0.0805	5.06	2.53	0.703	22.2	352.6	6.3

1) size of catchment area: 3600 km<sup>2</sup>

2) 1 ℓ s<sup>-1</sup> km<sup>-2</sup> is equivalent to 31.536 mm precipitation per annum.

3) at Fort Smith Airport

# PRECIPITATION AT HAY RIVER, 1945-1983 in per cent of 1951-1980 NORMAL (FOR CALENDAR YEAR)

below normal	normal (12 yrs)	above normal (7 yrs)	(5 yrs) 5 yrs   normal   6 yrs below normal
