

This worksheet contains a timeseries plot of model results for the proportion of effluent in Snap Lake, based on the Lower Bound minewater discharge scenario.

Figure 2-2 Proportion of Treated Effluent in Snap Lake Based on Predicted Treated Effluent Discharge Rates from the Lower Bound Scenario

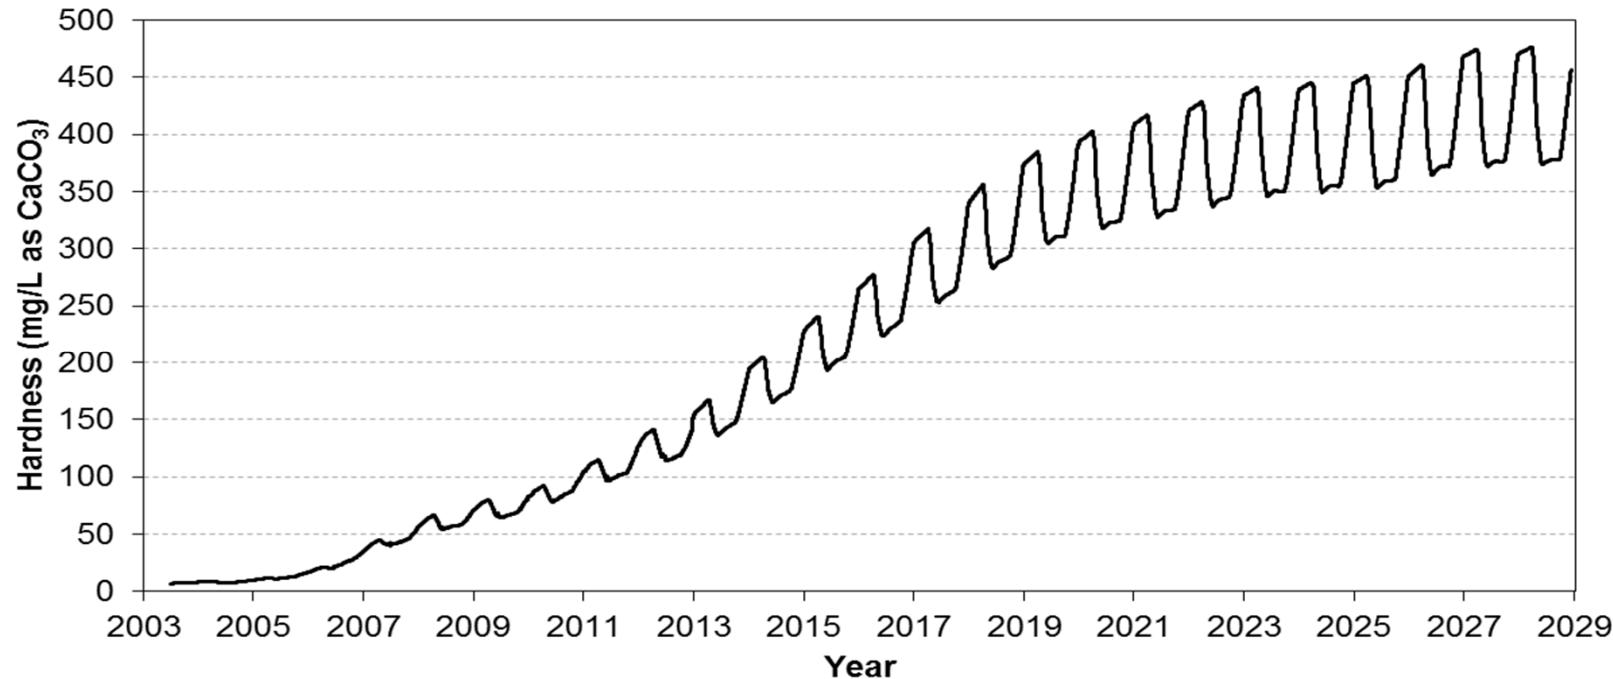

Note: Based on whole-lake average concentrations in Snap Lake.

je scenario.

'io

This worksheet contains a timeseries plot of model predictions for hardness (derived from predicted calcium and magnesium in Snap Lake). The model predictions are for Lower Bound Scenario B.

Figure I-1 Predicted Hardness Concentration in Snap Lake

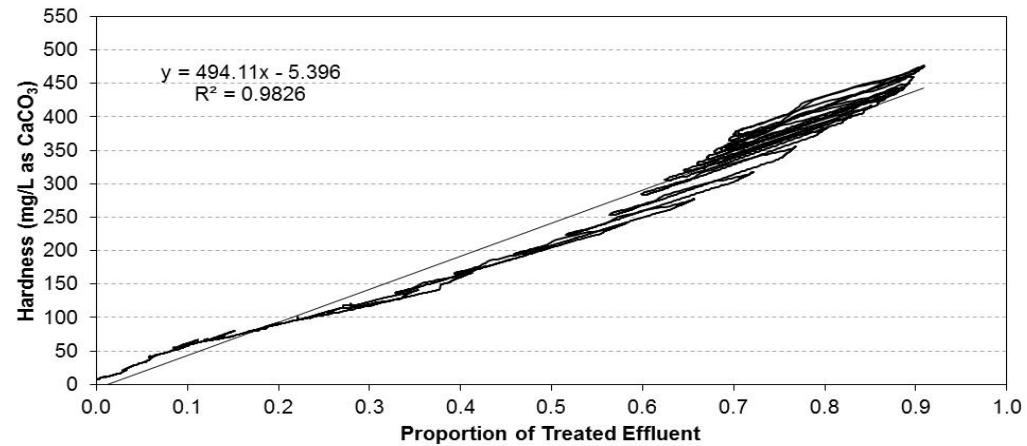

Note: Based on whole-lake average concentrations in Snap Lake.

mg/L = milligrams per litre; CaCO₃ = calcium carbonate.

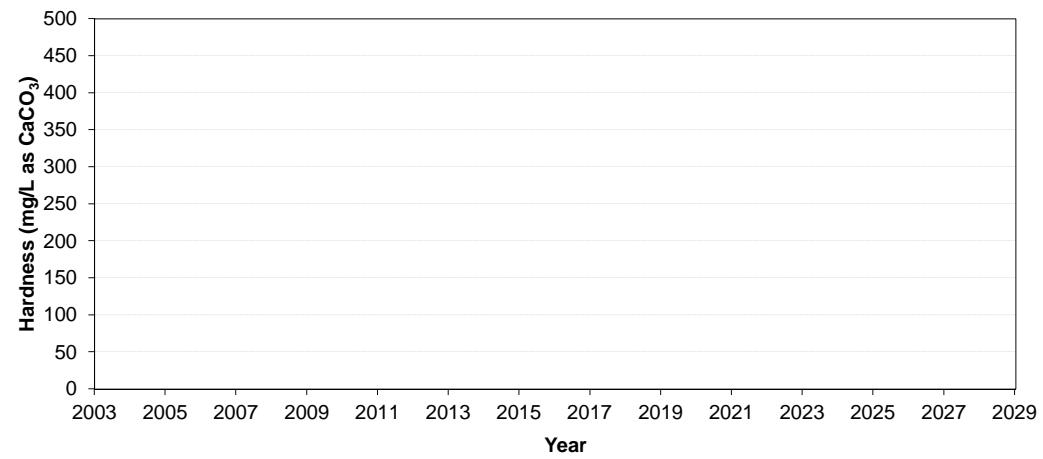

This worksheet contains the relationship between hardness and the proportion of effluent in Snap Lake.
As the proportion of treated effluent in Snap Lake increases, the hardness of Snap Lake water increases

Figure I-2 Correlation between Hardness Concentrations and the Proportion of Treated Effluent in Snap Lake

Note: Based on whole-lake average concentrations in Snap Lake
mg/L = milligrams per litre; CaCO_3 = calcium carbonate

	0.80	400	429	526	376	713	476	21,422
	0.90	450	429	473	338	640	427	19,226

Note: The effluent quality criteria in the highlighted row were recommended for the Mine

a) Calculations were based on an average predicted treated effluent discharge of 57,013 cubic metres per day (n^3/d) (average predicted treated effluent discharge during the year of maximum discharge [2026]), a dilution factor of 12 (volumes of lake water that mix with one volume of treated effluent), and on the assumption that four samples were collected per month (equivalent to sampling frequency in De Beers Water Licence of once every six days).

b) Long term average concentrations were calculated assuming an averaging period of four days

AEMP = Aquatic Effects Monitoring Program; mg/L = milligrams per litre; CaCO₃ = calcium carbonate.
