## TECHNICAL MEMORANDUM

---

**TO:** Julie L'Heureux – De Beers Canada 1780

**FROM:** Houmao Liu  
Dong Ding

**DATE:** 3 October 2013

**SUBJECT:** Predicted TDS Concentration in Mine Water Discharge Based on Calculated TDS Values

---

### INTRODUCTION

In the 2013 Snap Lake groundwater model update, Itasca Denver, Inc., (Itasca) used a predicted groundwater flow rate to the mine from the groundwater flow model (Itasca 2013) and the measured TDS concentrations from 2008 to 2013 at various locations and depths to predict the TDS concentration of the mine discharge water. De Beers Canada and Golder Associates Ltd. (Golder) recently requested that Itasca update the predicted TDS concentration based on the calculated TDS concentrations provided by the laboratory ("Calculated TDS" hereafter) instead of the measured values.

The Calculated TDS were available for the data set in 2008 and 2010 but not for the 2013 data set. The Calculated TDS for the 2013 data set were estimated as follows:

1. Established a linear correlation between the Calculated TDS versus the measured TDS concentration based upon the 2008 and 2010 data set (provided by De Beers on 1 October 2013).
2. Obtained the ratio of Calculated to measured TDS from the linear relation (0.9258 as shown in Figure 1).
3. Used this ratio to estimate the Calculated TDS for the 2013 data set.

Tables 1 and 2 summarize the measured and Calculated TDS values for 2008 and 2010, and 2013, respectively. For your reference, the geometric mean and arithmetic mean of the TDS values using the Calculated TDS is about 7% less than the means using the measured TDS values. The Calculated TDS values were used for the prediction of the TDS concentration in the mine discharge. The detailed description of the calculation was discussed in Itasca (2013).

Instead of providing all of the sensitivity simulations described in Itasca (2013), Itasca has provided the results of two groundwater model simulations based on the discussion with you. One simulation is the Base Case. The other is the simulation that assumes the hydraulic conductivity values of structure zones related to the Crackle and Snap faults outside of the current mining extent were increased by an order of magnitude from the Base Case (which was referred to as Simulation 4 in Itasca (2013)). The predicted inflow rate for the Base Case and Simulation 4 are summarized in Tables 3 and 5.

For each of the groundwater model simulations, the TDS concentrations in the mine discharge were estimated using both arithmetic and geometric mean values of the Calculated TDS. The predicted TDS concentrations of the mine discharge are summarized in Tables 4 and 6, respectively for both flow simulations.

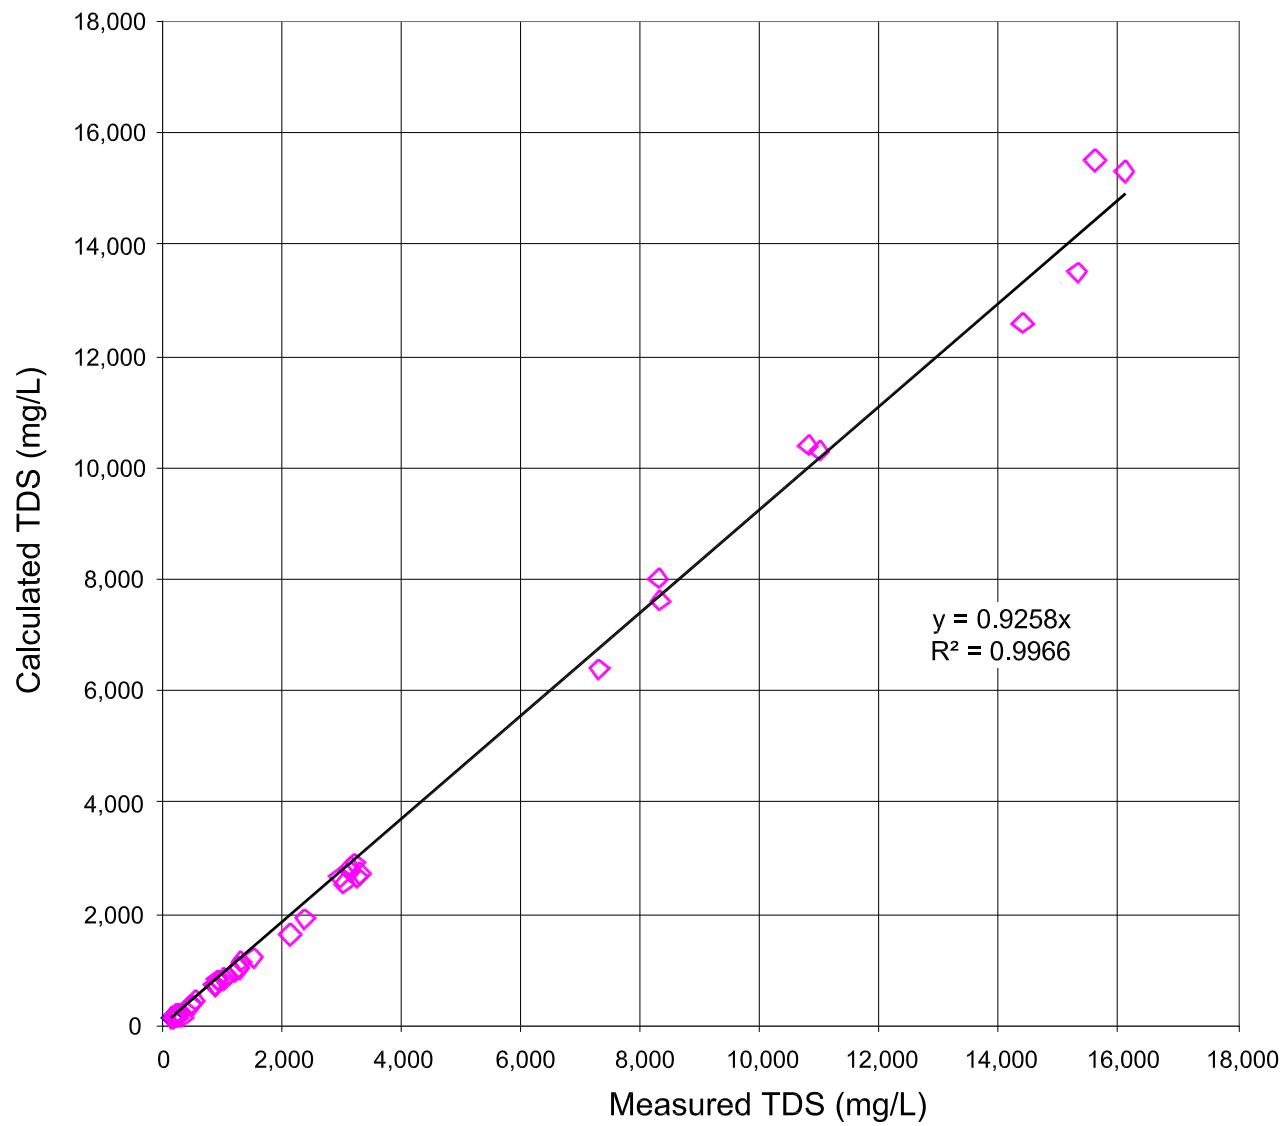

## CLOSURE

Itasca hopes that this memorandum addresses your needs. Please contact us if you have any comments or questions.
